This article examines the evolution of attitudes, concepts and ethics concerning environment and development. It also defines 'environment' and 'development' and the evolution of environmentalism, the green movement and green politics. It further explores why environment and development interest took-off between the mid-1960s and 1974 and discusses global environmental change and the possibility of an environmental crisis. The coverage includes neo-Malthusians; Limits to Growth debate; sustainable development, the Precautionary Principle, the Polluter Pays Principle. The article also discusses changes in environment and development attitudes between 1972 and 1992 especially the growth of popular, business and media interest ("greening"). It examines growing worries about transboundary environment and development problems (e.g., global warming). It reviews achievements of the UN 1992 Rio 'Earth Summit,' including *Agenda 21*. It notes the growing awareness of environment- and development challenges have prompted development of environmental management.

Environment and Development

Since the 1950s people have become aware of problems like wildlife extinction and pollution. However, before the early-1970s few, except ecologists and other environmental scientists, were familiar with the terms 'environment' or 'development.' Today those terms are in wide usage and it is accepted that for development to be successful it must be environmentally sensitive (Barrow, 1995).

The Term 'Environment'

'Environment' may be defined as the total external conditions and influences affecting the life and fortunes of organisms, effectively 'the parameters of life.' It is shaped by living and nonliving elements that often interact in complex ways, making it a challenge to understand and predict future situations. The study of these interactions, 'ecology,' was founded in 1869 by Ernst Häckel, became established by the 1930s, and expanded from the 1970s. Ecology is often used loosely as a label for environmental concern.

Humans can adapt well to the environment they live in, and may be able to modify it to better suit their needs. But often they fail to improve or even sustain conditions, cause environmental degradation (local and even global) and then have to move away or suffer. A given environment may offer more opportunities than others but, ultimately, there are limits to human activity. If humans can satisfy their needs on a sustained basis without damaging the environment they may be said to have achieved 'sustainable development.' There are often a number of workable development strategies that could be pursued, some 'fit-in' with nature and at the other extreme some boldly change conditions. Wise development should also assess and prepare for environmental threats. Agriculture seeks to modify environments by inputs of energy (human labor or fuel-based mechanization), technology, and knowledge to sustain higher outputs of food or other crops.

People often talk of 'their local environment,' which is part of one global environment or biosphere. The biosphere can be subdivided into a vast number of more or less interacting 'ecosystems' (each a recognizably distinct assemblage of organisms adapted to particular environmental conditions). The ecosystem is the basic functional unit of ecology.

The Term 'Development'

Attempts to define 'development' reflect the current values of those making the definition, it is therefore difficult to agree one definition that is universally accepted and precise. Some see it as a learning process; others argue it is 'positive social transformation.' Another definition that is widely accepted is: *an ambiguous term for a multidimensional process involving material, social and organizational change, accelerated economic growth, the reduction of absolute poverty and inequality*. There is some overlap with *modernization*, so a group of people could develop yet remain unmodernized, or vice versa (Leys, 1996). Modernization is generally accepted to be a change toward a 'modern' economic, social and political system evolved in Western Europe and North America between the seventeenth century and present. Some argue that there has been a paradigm shift since the mid-1960s, from modern to *postmodern* development, involving less support for a mechanistic, reductionist and compartmentalized approach to the world's problems, in favor of a more *holistic*, multidisciplinary stance. (A researcher adopting a holistic approach seeks to study the whole, which may be more than the sum of the parts, so exploration of linkages and interactions is as important as studying component parts.)

Attitudes toward Environment and Development

Peoples' perception of development affects their exploitation of the environment. It is frequently argued that a faulty attitude toward development leads to environmental misuse and socioeconomic problems for humans (*see* Nature and Society in Geography).

Attitudes toward Environment and Development from Prehistoric Times to AD 1800

Before humans developed a sedentary lifestyle and their numbers increased beyond a few persons per square kilometer, environmental damage was largely temporary and limited. People moved on before pollution or erosion became too bad and, with the possible exception of some game animals, seldom overexploited resources. Although it has always been important to recognize natural threats and opportunities, the need to be concerned has grown as people have settled and multiplied, and as industry and technology have caused new demands and impacts.

People, with few alternatives to fall back upon, often evolved sustainable livelihood strategies and sound rules of environmental stewardship to ensure resources were not degraded. However, the poor may be forced to sacrifice sustainable livelihood and future opportunities to survive in the short term unless given aid and more affluent people may cause havoc through environmentally insensitivity.

In medieval Europe, the view was that the universe reflected Divine Perfection, consequently there was little attempt to think about development before the Renaissance. One of the first to consider the shaping secular human development was Thomas Moore, who published *Utopia* in AD 1516. By the mid-sixteenth century Europe's merchant class had grown in influence, possibly assisted by the spread of Calvinistic ethics (Weber, 1958). There was a growing, relatively liberal, capitalist economy and an increasing interest in science and rational study. From the mid-eighteenth century commerce, scientific reason, Industrial Revolution and urban migration had caused huge changes of attitude: a shift to the 'modern' outlook. This modern Western outlook is often accused of insensitivity toward the environment. However, there are environment and development problems in virtually all societies: in atheistic, Christian, Islamic, Buddhist and Hindu countries, regardless of whether the economy is socialist or free-enterprise capitalist.

Beyond the spreading cities, degraded farmlands and forests of Europe and eastern North America several islands began to suffer damage to biota and environment by the eighteenth century. So, by the 1760s efforts were made to try to protect forests on Tobago, Mauritius, and St. Helena, and some other islands. Even some oceanic fisheries, seal and whale stocks were under pressure by 1800. Naturalists in Europe and the Americas raised public interest in the environment (an early example being Gilbert White's 1798 study of nature) (for writings on the development of environmental attitudes see Wall, 1994). Nevertheless, if there were problems there was plenty of new land and resources to move on to.

Attitudes toward Environment and Development from AD 1800 to the 1940s

By AD 1800 the dominant attitude adopted in Western nations was that, whenever possible, the environment should be developed (exploited), and unspoiled areas were wasted or were even threatening. As the nineteenth century progressed the idea that humans could conquer environmental problems became established. Between 1830 and 1930 engineering and science made huge progress, but as pollution and population increased (see Ponting, 1991) and as scientists learnt more, it became clear that controlling the damage to environment would be difficult.

In Europe, Russia and North America growing cities, pollution and the clearance of forest and wilderness prompted a diverse group of intellectuals, romantics and 'protoanarchists' to question the way development was progressing (these included Thoreau, 1854; Kropotkin, 1899). Some saw the need to value nature for the inspiration and solace it could give.

The idea of safeguarding the environment against development existed in a localized ad hoc way before 1800, people protected certain plants or animals, establishing sacred groves, hunting parks, and enforcing taboos. However, by 1840 a growing number of naturalists, hunters, and foresters could see that what had once seemed limitless lands and resources were being degraded so they set up societies to promote larger-scale conservation and protection. National parks and reserves began to appear in the USA, Africa, India and other countries, and a number of forestry services were established. In the USA *preservationists* like John Muir worked to establish unspoilt wilderness reserves, and *conservationists* like Gifford Pinchot argued environmental protection could be combined with compatible resource exploitation (*see* Environmental Policy: Protection and Regulation). On both sides of the Atlantic nongovernmental organizations (NGOs) were established after 1830 to promote conservation and wildlife protection (like the Sierra Club – founded in 1892); some of these bodies played an important role after the Second World War in establishing powerful new environmental NGOs like the International Union for the Conservation of Nature and Natural Resources (IUCN).

Publication of Darwin's *The Origin of Species*… in 1859 helped established concepts like 'natural selection' and evolution, which encouraged some to argue that the human environment-development relationship was influenced or even controlled by physical conditions like climate. Race was also often seen as another determinant of development (*see* Environmental Determinism). These *environmental determinists* have been divided into the 'scientific' (e.g., Huntington, 1915), who tried to explore how nature might affect human fortunes, and those who promoted more 'crude and subjective' arguments. Supporters of *social Darwinism* argued for development to be shaped by competition and eugenics, rather than mutual aid and tolerance of the less developed (Pepper, 1984). Much discredited by the 1940s, it is probable that these concepts helped discourage social scientists from exploring environment and development issues until well into the 1970s (see Barrow, 2003: 12–31).

Serious drought and soil degradation in the US 'Dustbowl,' especially between 1932 and 1938, displaced many farmers. Novelist John Steinbeck drew on the misery caused by the disaster for his novel *The Grapes of Wrath* (1939), as did the folksinger Woody Guthrie; both were at first seen as subversives criticizing the American lifestyle (development dream) before they provoked public concern. The US Government had begun 'New Deal' measures to control regional land degradation by the mid-1930s, notably the foundation of the US Soil Erosion Service (in 1933) and its successor, the US Soil Conservation Service (in 1935). Just as the public in North America and Europe had started to see signs that there were environmental limits to development the Second World War and Cold War diverted attention and resources.

Attitudes toward Environment and Development after the 1940s

Between 1945 and the 1980s attention was focused on economic and industrial reconstruction, improving food production and the Cold War. Detonation of atomic bombs in 1945 signaled an ability to cause huge environmental damage. Major environment disasters took place: oil-spills, nuclear accidents, and other problems. The Cold War diverted attention and funds from environmental studies and development programs; but by triggering antinuclear weapons protest movements, it also helped to establish environmental politics in Europe. A few explored environment and development issues in the 1940s and 1950s (e.g., Teilhard de Chardin and Aldo Leopold), and some NGOs and public figures began to bring conservation and pollution issues to the attention of the public in North America and Europe. In 1949 the UN held one of the first postwar meetings, the Conservation Conference at Lake Success, New York State. In 1948 the IUCN, an NGO which has acted as a very influential network supporting conservation and environment and development issues was founded, now known as the Union for World Conservation, it continues to be important.

By the early-1960s attitudes toward environment and development had begun to change in Western nations, this is probably attributable to peoples' growing affluence and leisure time, development of the media, improved knowledge of the structure and function of nature (in part thanks to the exchange of information and research during the International Geophysical Year of 1957–1958 and the International Biological Program of 1964–1965), and diminishing colonial control. Rising levels of atomic weapons test fallout led by the 1960s to popular environmental fears. It has been suggested that the US Civil Rights Movement and 'hippie' culture encouraged people to ask questions about development and to value the environment more. Another significant development was that NGOs and groups of concerned individuals began to fight environmental issues in law courts. Interest in environmental matters 'took-off' in California, spreading to the rest of North America and Europe, reaching a peak between about 1966 and 1974. During this period what is variously described as 'environmentalism,' an 'environmentalist movement,' an 'environmental movement,' or an 'ecology movement' spread. A number of popular books helped provoke public interest, one of the most seminal and earliest being *Silent Spring* (Carson, 1962), which voiced concern about dichlorodiphenyltrichloroethane (DDT) pollution.

Today *environmentalism* is generally seen as a moral code or set of mediating values to guide human conduct. Environmentalism is often confused with *ecologism* which is more of a political ideology requiring its adherents to seek ethical and moral changes and to move away from giving priority to the welfare of humankind in any evaluation of development options. Environmentalism generally allows followers to put humans before nature and to seek managerial solutions rather than make far-reaching changes of development ethics and morals. Environmentalism encompasses a huge diversity of beliefs and attitudes, some pragmatic and willing to draw-upon technology (light green), others more romantic and suspicious of science. In general mid-1960s to mid-1970s environmentalism was dogmatic, rich in advocacy rather than workable proposals, and focused on the need for conservation, and the threats of overpopulation, pollution, corporate insensitivity and careless technical innovation (Farvar and Milton, 1972; Schumacher, 1973), it was also largely unpoliticized and restricted mainly to middle classes and intellectuals (*see* Political Ecology: Anthropological Perspectives). Many environmentalists, especially the *neo-Malthusians* (e.g., Ehrlich, 1972), warned of a coming 'crisis.' The feelings of 'crisis' were fanned when the USA and USSR space programs released pictures of Earth from space, prompting awareness that war and development took place within a finite, vulnerable system - 'Spaceship Earth.' At about this time the Club of Rome published *The Limits to Growth* (Meadows et al., 1972, 2004), which argued that in a finite world growth focused development was akin to cancer and zero-growth was needed. Amidst bitter debate this helped initiate a rethinking of development ethics and the nature of economics. Although it's roots lay in the 1930s the *Green Revolution* took-off in the 1960s, faltering and changing after 1973 (when oil-based inputs soared in cost). This was an initially clumsy attempt to use science and western development skills to raise agricultural production without clearing new land – i.e., intensification. Results were variable and after the 1990s the Revolution changed character as it learnt from mistakes and new knowledge, sustainability concerns and genetically modified organisms (GMOs) appeared (see Conway, 1997).

Warnings that the Earth faces an environmental and developmental crisis have increasingly been issued since the 1960s. The cause is identified as one or a combination of the following: population growth; cavalier use of nature; misapplication of technology; faulty development ethics. Environment and development problems can be expensive, socially damaging, or impossible to solve once they happen, it therefore makes sense to try to recognize and monitor crucial thresholds and act to prevent a crisis (a turning-point after which action is less effective or hopeless); yet there are risks in warning of threats and acting before there is proof unless a so-called 'win–win' approach can be found which gives benefit whatever the outcome. There are risks also that accepting there is a crisis might divert attention or promote undesirable 'crisis management,' rather than careful problem avoidance. Recognition of a crisis may be a mistaken overgeneralization and lead to failure to uncover causes.

In 1973 the UN Environmental Programme (UNEP) was established to promote environmental care worldwide. North America and Europe started to pass legislation in the late-1960s to develop more proactive planning which aims to reduce or avoid problems. One important examples of such legislation was the 1969 US National Environmental Protection Act (NEPA), among its achievements was the promotion of *environmental impact assessment* (EIA) procedures, and within 10 years it had been copied in most countries around the world. By 2010 EIA methods had improved and practitioners were policed by bodies like the International Association for Impact Assessment.

In spite of continuing environmentally damaging accidents, growing politicization of environmentalism, and the 1972 UN Conference on the Human Environment (held at Stockholm), popular interest dimmed between about 1974

and the late-1980s. The 1973–74 Organization of the Petroleum Exporting Countries (OPEC)-precipitated oil crisis and unsound international lending helped get many poor countries into debt by the 1980s, prompting increased exploitation of natural resources to earn foreign exchange which accelerated environmental damage also, as funds became scarce, poverty grew and the poor often resorted to environmentally damaging livelihood strategies. A response to debt was often structural adjustment which led to pressures on natural resources. Political changes in the USA by the late-1970s saw less government enthusiasm for expenditure on environmental protection, although there had been international agreement on a (nuclear weapons) Test Ban Treaty which reduced atmospheric fall-out levels.

Attitudes toward Environment and Development after the 1970s

At the time of what was effectively the first international ecology 'summit,' the 1972 UN Conference on the Human Environment at Stockholm, environmental matters were poorly reported, environmentalism was hardly politicized, few states had ministries or departments for the environment, and there was disinterest or even fear of calls for limits to growth and to protect nature. A number of representatives, especially those from developing countries, voiced the views that environmental care was a luxury their nations could not afford; that it was a ploy used by the rich to delay further development and subjugate or to exploit them; or, was hypocrisy coming from states which had damaged the environment to grow rich. When the 1992 UN Conference on Environment and Development met at Rio de Janeiro virtually all countries had ministries of environment; most delegates accepted environmental concern was a vital, integral part of development and not a luxury; the prevailing view was that rich and poor countries were interdependent parts of one global environment; and that practical and possibly painful measures must be taken to solve problems and promote more development in poor countries. In 20 years there had been a 'sea change.'

Certain publications helped achieve this shift, one was *Our Common Future*, the 'Brandt Report' (Independent Commission on International Development Issues, 1980), which spread the idea of developed and developing country interdependence eroding the view 'aid is charity.' Other influential publications included: the *World Conservation Strategy* (1980) and the 'Brundtland Report' (World Commission on Environment and Development, 1987). These publications rekindled public interest in environment and development issues; they also spread the concept of *sustainable development*. Sustainable development was more palatable than zero growth; it links aid, environment and development in a concept which, although difficult to give a precise and universal definition for, argues for stewardship to minimize environmental and social damage, efforts to ensure future options are not reduced and, if need be, aid to help achieve these aims.

During the 1980s the 'shorthand' *green* was increasingly applied to environmental issues. The meaning is vague, but in the main stands for environmentally friendly and environmentally sensitive, so 'greening' means 'improving environmental care,' and a 'green,' someone concerned for the environment (Adams, 2009). 'Greening' has marked the spread of environmental concern to a wider spectrum of Western (later other) societies, than in the 1970s. Interest spread to the public as a whole, and business, the legal profession, technology, the media, consumer protection bodies, marketing and advertising, economics and social studies, gender studies, tourism, theology and philosophy have 'gone green.' This is especially important with respect to economics and commerce, given the crucial role these have in development: an early green economics publication being *Blueprint for a Green Economy* (Pearce et al., 1989). By the late-1980s many bodies, including the World Bank and most aid agencies, had established environmental departments and green development guidelines.

Many interpret this greening as a new social movement: the *green movement*. Some see the green movement as a 'cultural attack' on the ills of modern society and economics, and it has been argued it is a manifestation of a postmodern and post-industrial cultural shift. The green movement (light green – deep green) is very diverse, but most would accept it embraces environmental sensitivity, social responsibility, grass-roots democracy, and nonviolence. However, greens may not be objective and even scientists may misjudge or apply received wisdom (see Lomborg, 2001) and sometimes business and institutions deliberately promote environmental falsehoods to look good ('greenwash').

Many greens scorn politics, or support whatever party they feel will best protect the environment; however, an aspect of greening has been the spread of environmental politics. Green politics first originated in New Zealand and West Germany with roots in antinuclear weapons protest, feminism, and the US Civil Rights Movement, early romantic environmentalists (like Henry Thoreau), and more recent writers on *social ecology*, environmental ethics (such as Arne Naess). Starting in Hamburg during the early-1970s, green candidates were elected to German State legislatures, and then the national Parliament. Early German activists include Petra Kelly and Rudolph Bahro. Only scatterings of greens have been elected to governments in Europe and other countries (virtually none in the USA), and if anything support has waned since the mid-1980s, however they triggered a greening (somewhat cynical) of established political parties. There is now scarcely a single country without green NGOs (increasingly networking globally), sympathetic newspaper, radio and television editors, and politicians interested in cultivating an environmentally sensitive image, and growing commercial interest in the environment.

Some recognize the threat to life and development of catastrophic natural events and advances in science. From the 1970s there has been more interest in terrestrial and extraterrestrial threats and the need to respect nature and its limits: in 1969 James Lovelock proposed the *Gaia hypothesis*, there are variants, but all argue that life on Earth has not simply adapted to physical conditions but is part of a complex interrelationship. If the hypothesis is accepted, the implication for development is that humans must 'fit in' and not upset mechanisms that maintain the environment or face catastrophic ecological change (*see* Gaia). In 2006 Lovelock stressed that Gaian limits had been exceeded but that avoidance of the catastrophic results was just possible. He argued technology would be vital in this and that cautious sustainable green

approaches might be too slow and so threatens survival (Lovelock, 2006).

Around 2000 many activists and institutions undertook stocktaking and some drew-up goals, notable among these were the Millennium Ecosystem Assessment - an international program launched in 2001 by the UN and completed in 2005 that aimed to provide information on environmental change and human well being. The findings indicated worrying damage to the biosphere that threatens future development. In 2000 the UN published the 'Millennium Development Goals 1990–2025.' By 2010 business and institutions were applying social responsibility and corporate environmental responsibility in their policymaking and the use of ecoauditing was expanding (e.g., ISO 14001 and the European Eco-Management and Audit System - EMAS).

Starting in the late-1980s and possibly catalyzed by the 1998 El Niño event (a periodic ocean/climatic fluctuation) and the 2004 Southeast (SE) Asian tsunami there has been a revived interest in environmental influences on development. This neoenvironmental determinism has drawn on archaeology, history and paleoecology: for example studies of climatic change impact on past civilizations (see Diamond, 2005). These studies might help reveal why adaptability is important and suggest ways people in the past deployed sustainable agriculture strategies that we might usefully reengineer today (such as using bio-char). By 2013 limited efforts were being made to develop early warning of meteorite, comet and asteroid strikes on Earth and of storm, volcanic and earthquake events.

At the time of writing it is apparent that 'development pressures' are damaging, or have destroyed, established livelihood strategies, leading to environmental damage and human misery. For example, the spread of sedentary agriculture has disrupted nonsedentary agriculturalists; economic policies may trigger land degradation; population growth or land development policies may promote settlement of unsuitable and vulnerable soils. Globalization has increased (once local activities are linked to and more and more dependant upon and at risk from distant manufacturing, research, transport, world trading patterns, influences, etc.). The world in the twenty-first century is more crowded and urbanized than ever before reducing resilience and making adaptation difficult. Environmental change and human actions might generate large numbers of ecorefugees, who on relocation may cause further environmental and socioeconomic problems (Black and Black, 1998). As traditional ways breakdown new ones must be found which improve and sustain human welfare without environmental damage. While the Cold War threat receded after 1985 there are new concerns: terrorism, rogue states and organizations acquiring nuclear, chemical, biological and computer warfare capability.

Governments, business, and NGOs increasingly adopt *environmental management* measures to try to ensure the *polluter pays* (i.e., whoever is responsible for environmental damage meets the cost of remedy) and minimize unwanted impacts, using precautionary techniques like environmental and social impact assessment, environmental accounting, and ecoauditing. Foreign aid is nowadays almost always conditional on the application of such measures to try and reduce or avoiding environment and development problems. Since the late-1980s concern about *transboundary environmental problems* has increased, these include acid deposition; stratospheric ozone depletion; chemical pollution; reduction of oceanic fish stocks, loss of biodiversity; and above all global warming. There has been progress in understanding the structure and function of the environment and in techniques for measuring and analyzing data-for example, satellite and drone remote sensing and geographical information systems (GIS) (for handling constantly updated data). The mobile phone is having a growing impact on how people perceive their environment, make their living and can react to environmental threats and degradation. At the Rio 'Earth Summit' in 1992, participating nations signed a Declaration on Environment and Development, Conventions on Biodiversity (protection) and Climate Change (control), and endorsed an environment and development action program: *Agenda 21* (Keating, 1993).

Since the 1990s fear has grown about environmental change, particularly global warming (greenhouse warming) and to a lesser extent sea-level rise, runaway changes to climate and ocean nitrification. Attempts to achieve international controls have initiated agreements like the Kyoto Protocol (started in 2005 and ongoing). Concern for climate change increasingly influences development efforts although some have ignored or resisted. There are increasingly controls on trade, technology, and taxation, aimed at reducing carbon dioxide and methane emissions that would have been unthinkable 30 years ago. Planning for global warming impacts is underway (e.g., Stern, 2009) and fear that present-day countries are less adaptable and more vulnerable to environmental change than were past peoples. Clearly, one development goal should be to seek better adaptability and resilience. Another twenty-first century challenge is from GMOs – microorganisms, plants, and animals that contain recombinant DNA and may have huge agricultural, healthcare or industrial potential. GMOs could raise food production, counter pollution and global change and have medical value, but if poorly managed they might threaten environment, human health and livelihoods. A treaty – the Cartagena Protocol on Biosafety was started in 2002 to try and improve assessment and management of GMO risks and potential.

Nations increasingly negotiate solutions for environment and development problems, but often back-off when it comes to spending money or foregoing profits. Governments and individuals are aware that consumption and technological advances can mean environmental damage and there are better monitoring and enforcement of controls but fear of an environmental crisis grows.

Abstract

This article examines the relationships between human populations and the natural and physical environment. Because of the coupled relationships between human health and the environment, global institutions such as the World Health Organization have intervened to prevent infectious and noncommunicable diseases by attending to their social and ecological determinants. It is generally accepted that human health depends upon a sustainable environment that provides opportunities for healthy decision-making and effective disease management. Multiple scholarly disciplines attend to health and environment interactions, including the fields of environmental health, social epidemiology, medical geography, and political ecology. Additionally, activists and policy-makers have received international attention by showing how human health is affected through disproportionate exposure to positives and negatives within the surrounding environment. Whether this means proximity to facilities that produce toxins and pollutants or access to green space and bikeways that promote healthy lifestyles, these factors have contributed to the linking of health with concerns for social and environmental justice.

Human health is intricately connected to the environment. This recognition includes the natural environment and a range of biotic and abiotic factors, as well as the physical or human-built environment that facilitates the spread of infectious disease or the production of conditions that influence noninfectious, or noncommunicable, disease. As one example, malaria is transmitted by *Anopheles* mosquitoes that serve as the main vector for human populations. These mosquitoes are highly dependent upon the natural environment, specifically in terms of precipitation and temperature that can alter the environmental conditions that allow for their survival. Recent work has shown that daily fluctuations in temperature affect parasite infection, the rate of parasite development, and components of mosquito biology that combine to determine the intensity of malaria transmission (Paaijmans et al., 2010). Daily temperature changes have also been shown to play a role in dengue virus transmission by the *Aedes aegypti* mosquito (Lambrechts et al., 2011). Specifically, mosquito life span and susceptibility to dengue infection decreases when there are larger fluctuations in daily temperature as compared to only moderate daily temperature variations. The implication is that human and nonhuman species are directly impacted by the natural environment. Additionally, these coupled relationships are dynamic and can shift because of variations in temperature, precipitation, or ecosystem functioning.

Other infectious diseases with an unknown etiology are credited with being produced by the natural environment. The pathogen *Mycobacterium ulcerans* is the causal agent for Buruli ulcer disease, which is one of the most frequently occurring human mycobacterial diseases (Qi et al., 2013). Ongoing research is working to show how anthropogenic impacts on the natural environment, particularly land cover disturbance and climate change, could trigger human exposure to the pathogen. In addition to the ecological patterns, Buruli ulcer is also potentially involved with social systems such as livelihood production and settlement patterns. These three examples of malaria, dengue fever, and Buruli ulcer disease show that the transmission of infectious disease to human beings is related to nonhuman species, temperature, precipitation, and other drivers within the surrounding environment.

International agencies emphasize the role of the natural and physical environment in producing hazards such as those caused by unsafe drinking water or exposure to toxins and air pollutants. According to the World Health Organization, within developing countries, the primary environmentally caused diseases are diarrheal disease, lower respiratory infections, unintentional injuries and accidents, and malaria. Within wealthier and industrialized countries, cancer, cardiovascular disease, asthma, lower respiratory infections, and traffic injuries are major health hazards. According to the World Health Organization Public Health & Environment Global Strategy Overview (2011), environmental hazards are responsible for roughly a quarter of the total burden of global disease. In developing countries, the burden of environmental hazards is more strongly experienced by communicable diseases, such as malaria, dengue fever, and human immunodeficiency virus (HIV). In developed countries, environmental hazards are believed to have a larger impact upon noncommunicable diseases.

The central areas of emphasis for the World Health Organization in dealing with public health and the environment include improvements in water, sanitation, and hygiene to prevent waterborne diseases such as cholera. Indoor air pollution deriving from fuels and cook stoves, in addition to outdoor air pollution resulting from urban transportation and population growth, are also emphasized as requiring intervention and policy responses. Lastly, the World Health Organization notes the need for chemical regulation policies that reduce exposure from industrial and agricultural activities (World Health Organization, 2011). These types of environmental health dynamics attest to the role of unsustainable development practices in making certain populations vulnerable to illness.

The United Nations has recently emphasized the role of noncommunicable human diseases as the primary cause of death and disability in the world. Roughly two-thirds of annual

deaths are caused by cardiovascular diseases, cancers, chronic respiratory diseases, and diabetes. Because many of these can be prevented, public health experts emphasize the importance of reducing tobacco use and alcohol, unhealthy diets, and a lack of exercise. In terms of noncommunicable disease, there are a variety of behavioral and physical environmental conditions that support their expansion. There has been a growth of popularly written books that link the relationships between food production and consumption patterns with human well-being. Michael Pollan (2006), Eric Schlosser (2001), and Marian Nestle (2006) have received attention for suggesting that changes to food decision-making are needed to reduce obesity, dependence upon pesticides and oil, and support local economies and environmental systems. Central to this argument is that industrialized food production in the United States, particularly the dependence upon corn, has triggered infrastructure and cultural shifts that have repercussions for human health.

Environmental Health

A number of academic and policy fields study health and environment interactions with the intention of detailing effective interventions to ensure sustainable and viable possibilities for human well-being. Infectious diseases are connected to the natural environment and changes to global climate dynamics. The field of environmental health examines how human health is affected by the natural and physical environment. The disciplines of environmental epidemiology, toxicology, and exposure science are often recognized as central to environmental health. Environmental epidemiology studies the relationship between environmental exposures, such as chemicals, radiation, microbiological agents, and human health. Toxicology studies show how these exposures lead to specific health outcomes. Finally, exposure science examines human exposure to environmental contaminants by both identifying and quantifying exposures. In addition to these research fields, social science disciplines, such as social epidemiology, medical anthropology, and public health, have been influential in showing the specific connections between the natural environment and human health. The World Health Organization (2014) defines environmental health as the "physical, chemical, and biological factors external to a person, and all the related factors impacting behaviours. It encompasses the assessment and control of those environmental factors that can potentially affect health. It is targeted towards preventing disease and creating health-supportive environments. This definition excludes behaviour not related to environment, as well as behaviour related to the social and cultural environment, and genetics."

The field of epidemiology is also credited with making connections between human health and the surrounding environment. The work of Dr John Snow is widely recognized as advancing the science of germ theory through the identification of the cause of a cholera outbreak in Soho, England, in 1854. Snow mapped the incidence of the outbreak and interviewed local residents to identify the source as a water pump on Broad Street. The dismantling of the pump and subsequent cessation of the outbreak helped establish epidemiology as the foundation for public health while evidencing the relationships between the environment and human health.

Urbanization

The built environment is integral to human health. Within the United States, the expansion of the suburbs following World War II necessitated transportation to allow individuals to travel to employment and commercial centers. This transportation was largely the automobile with one consequence being an increasingly sedentary lifestyle that is credited with contributing to health challenges, such as obesity. Urbanization is also occurring on the global scale, with more than half of the world's population now residing in an urban area. The World Health Organization (2011) estimates that by 2050, 70% of the world's population will be living in towns and cities. While potentially increasing access to health care services and environmental benefits, in a public health bulletin the World Health Organization notes that urbanization could concentrate health risks while generating new hazards. Globally, road traffic injuries are the ninth leading cause of death, and most road traffic deaths occur in low- and middle-income countries. Urban air pollution kills around 1.2 million people globally each year, primarily due to cardiovascular and respiratory diseases. A significant proportion of urban air pollution is caused by motor vehicles, although industrial pollution, electricity generation, and in least developed countries, household fuel combustion are also major sources. Infectious disease, such as tuberculosis, can concentrate in large urban centers. In New York City, tuberculosis incidence is four times the national average. In the Democratic Republic of the Congo, 83% of people with tuberculosis live in cities. Lastly, the World Health Organization notes that urban environments are not always designed to support physical activity or promote healthy food consumption. Participation in physical activity is constrained by a variety of urban factors including overcrowding, high-volume traffic, heavy use of motorized transportation, poor air quality, and lack of safe public spaces and recreation facilities.

Another potential health effect with increasing urbanization is heat stress. Wilhelmi et al. (2013) assert that the urban heat island (UHI) effect is a leading cause of weather-related mortality in the United States and elsewhere. Different groups within the population are more vulnerable, specifically the young and elderly, and also those without access to air conditioning or other services that could mitigate the effects. It is anticipated that urban heat stress will intensify in the future with global climate change and an increasingly urbanized population.

While the global population increasingly urbanizes, there are still rural populations whose health and quality of life depend upon services that are not always available. In fact, one of the motivations for migration to urban environments is to seek out employment and social services that can positively influence human health. Within rural communities in the United States, there exist variations in proximity and ability to access health care centers, such as clinics or hospitals. One response has been the establishment of mobile clinics that extend the range of services for these populations.

Climate Change and Health

Anthropogenic climate change represents a significant challenge for the natural environment and human health. Variations in the amount, intensity, and duration of precipitation can alter the environmental conditions that allow certain disease vectors to survive. Additionally, temperature changes can shift the latitudes for ecosystems to support the movement of species into new areas. The Intergovernmental Panel on Climate Change (IPCC) Fifth Assessment Report (Smith et al., 2014) includes a chapter that addresses the links between global climate change and human health. The IPCC recognizes three pathways through which climate change affects health. The first pathway includes direct impacts that are tied to changes in the frequency of extreme weather including heat, drought, and heavy rain. The second pathway considers effects mediated through natural systems such as the role of disease vectors, water-borne diseases, and air pollution. As evidence of these effects, the report acknowledges that the spread of malaria in parts of Africa, or the West Nile Virus in the United States, demonstrates how infectious disease can accompany changing weather patterns. Lastly, the third pathway addresses effects heavily mediated by human systems, such as occupational impacts, undernutrition, and mental stress.

Climate change and health scenarios within the IPCC report suggest that there will be greater risk of injury, disease, and death due to more intense heat waves and fires. The report notes with high confidence that there will be increased risk of undernutrition stemming from reductions in food productivity and increased risks of food and waterborne disease and vector-borne diseases. The IPCC report also recognizes the social dynamics influenced by climate change that shape human health. Human populations could be disrupted due to rising sea levels, reduced access to environmental services, and agricultural decline. The report notes that until the mid-century climate change will most likely intensify existing health challenges in ways that affect the most vulnerable. The most vulnerable populations will likely have reduced work capacity and less productivity, which can cause a downward spiral into increased socioeconomic poverty. As such, the IPCC recommends addressing underlying social vulnerabilities to environmental change by investing in policies to increase access to clean water and sanitation, improve health care services including vaccination and child health services, reduce socioeconomic poverty, and improve the ability of populations to respond to disasters. The achievement of these goals will require substantial planning given that the IPCC recommends redesigning transport systems to promote active transport and reduce dependency upon motorized vehicles.

Political Economy and Environmental Health

Because health and environment interactions are mediated by social systems, the role of political, economic, cultural, and gendered dynamics in shaping health vulnerabilities and environmental sustainability have been addressed by a number of academic disciplines. The field of social epidemiology has demonstrated the social determinants of health and how these vary within settings. Medical anthropology has made a number of contributions on health and the built environment with one widely recognized element being how variations in access to disease and quality health care constitute structural violence against a population (Farmer, 1999). The field of medical geography has drawn upon disease ecology to examine how the natural environment, including features such as topography, vegetation, and climate, interact with vector and pathogen ecology to produce disease. These fields have been valuable in showing the role of social and ecological determinants in shaping human health and the ways that vulnerabilities vary across spatial and temporal scales.

Attending to the underlying conditions that contribute to the spread of infectious disease or facilitate noncommunicable conditions, scholarship has focused upon the structural and political economic dynamics that produce health inequalities. An early proponent of this approach was Meredith Turshen (1977: p. 48) who argued that disease ecology viewed economic and political processes to be irrelevant, and therefore suffered "from a failure to consider the relation of people to their environment in all its complexity." Building upon this with an examination of health and environment interactions in Tanzania, Turshen (1984) utilized a political ecology of disease approach to assert that historical and spatial systems were integral to human health and well-being. Specifically, she argued that the imposition of colonialism upon Tanzania transformed social and environmental systems in fundamental ways that would have lasting effects following the country's independence in 1962.

Within the social sciences, the research field of political ecology has documented the ways that political and economic systems shape environmental resource use and management. Political ecology has been identified as having five primary themes (Robbins, 2012), with one being the positioning of nonhuman actors into human systems to understand the resulting impacts for disease management. Political ecology has provided greater attention to environment and health interactions in recent years while drawing upon related scholarship from medical anthropology and health geography (King, 2010). Central to this wave of research is attending to the role of political and economic systems in producing disease vulnerabilities and differential health management capabilities. Disease discourses, including the meanings and practices that are inscribed within particular disease patterns, are also addressed by political ecology. Lastly, political ecologies of health also emphasize the coupled relationships between social and ecological systems in producing human health and well-being.

The reciprocal dynamics between social and ecological systems has been demonstrated with the HIV/AIDS epidemic. While research and policy have shown the ways in which the disease has impacted demographic patterns, national economies, and agricultural production, there are also ecological effects associated with the spread and management of HIV. Talman et al. (2013) identify a number of possible interactions between HIV and the natural environment, including the selling of livestock, land fragmentation, agricultural decline, and increased dependence upon natural resources as a coping mechanism. One of the emerging findings from current scholarship is the importance of food security in providing needed nutrition and vitamins to those infected with the HIV

virus. In work from central Mozambique, Kalofonos (2010) shows that adherence to antiretroviral therapy is tightly coupled with food needs and intracommunity tensions about who receives external assistance. While international public health and development organizations deserve recognition for increasing access to life-saving medications, the gamut of needs involved with HIV management indicate multifaceted interactions with the natural environment.

An additional way in which changes in the natural environment and human health are coupled is through an understanding of coproduction between humans and nonhuman species. Rather than focusing upon a unidirectional set of relationships, coproduction evaluates the ways in which nonhuman nature influences social systems. Scholarship has addressed how interactions with nonhuman species, such as a mosquito, results in adjustments by humans to manage disease outbreaks and public sentiment. In a case study addressing the management of *A. aegypti* and *Culex quinquefasciatus* mosquitoes in the state of Arizona, it has been shown that concerns about West Nile Virus have prompted different state responses ranging from surveillance and adulticide, GIS monitoring and larvacide, and education and public awareness (Robbins and Miller, 2013). As another example of this coproduction, Scott et al. (2012) examined the relationships between humans and pathogens, which they suggest are mutually conditioned due to continuous changes in exposures and institutional processes.

Health within Changing Environments

The post-World War II period marked the onset of emerging environmental concerns and legislation that were significant for coupling environmental health with human health. Particularly notable were the contributions from Rachel Carson who raised public awareness about the human and environmental dangers from pesticides in industrial agriculture. In *Silent Spring* Carson used her scientific training to argue that chemicals were becoming widely used for controlling disease and pests. She argued that the reliance upon these pesticides within the industrial agriculture, in addition to practices such as single crop farming and imported species, made human and nonhuman species vulnerable. Carson focused her attention upon dichlorodiphenyltrichloroethane (DDT) which had been converted from a preventative for malaria and typhus among soldiers to an agricultural insecticide following the conclusion of the war. Among the species directly impacted by DDT were ospreys and bald eagles, whose ability to reproduce was negatively affected due to the concentration of the pesticide in the food chain. When the bald eagle was adopted as the nation's symbol in 1782 there were 25 000–75 000 nesting pairs, however, by the early 1960s there were fewer than 450 pairs. The banning of DDT in 1972, coupled with the passage of the Endangered Species Act in 1973, is largely credited with the recovery of the bald eagle and other raptor populations.

In the wake of Carson's warnings and the first United States Earth Day in 1970, major pieces of environmental legislation were passed to protect the health and sustainability of the natural environment. These include the National Wilderness Act (1964), the Wild and Scenic Rivers and National Trails Act (1968), the Clean Air Act (1963), the Clean Water Act (1972), and the Safe Drinking Water Act (1974). The consequence has been an expansion of traditional environmental protection in the United States for particular landscapes, such as the creation of Yellowstone National Park in 1872, toward policy engagements that couple the possibilities for human health with the sustainability of the natural environment.

Environmental Justice

The relationships between the environment and human health are not equally experienced. The rise of case studies that show the disproportionate exposure to environmental hazards, such as proximity to facilities that produce toxins or pollutants, have helped establish links between health and social and environmental justice. One of the first incidents that brought public attention to environmental hazards was the Love Canal incident. Love Canal is a community in upstate New York that was built over 21 000 tons of toxic waste that had been dumped by Occidental Petroleum Corporation, which was previously Hooker Chemical Company. Historic rainfall caused the improperly stored containers to leach into the basements of 100 homes and a public school. This rainfall generated widespread concern because the landfill was believed to contain 82 different compounds of which 11 were suspected carcinogens at the time, including benzene. Declared a federal disaster area, residents organized to receive assistance in relocating, which was a process that unfolded for several years. In addition to raising public awareness as to the potential health hazards from unregulated exposure to toxins, Love Canal provided the catalyst for the establishment of Superfund Legislation that empowers the Environmental Protection Agency (EPA) to list and remediate toxic waste sites.

Following Love Canal, two cases helped advance the argument that disproportionate exposure to landfills and pollutants should be considered environmental racism. The announcement in 1978 that a landfill to store polychlorinated biphenyls (PCBs) was to be placed in Warren County, North Carolina, provoked widespread community protests against the decision. The Afton community, which was slated to be directly affected by the creation of the landfill, was situated in a region of high socioeconomic poverty and contained a largely African American population. Community residents organized nonviolent protests and attempted to use the court system to overturn the decision; however, the landfill opened in 1982. The second case was the Whispering Pines Sanitary Landfill which was intended to be placed in a largely African American neighborhood in Houston, Texas. In writing about the case, Robert Bullard (2005) noted that although African Americans made up 25% of the city's population at that time, the five city-owned landfills (100%) and six of the eight city-owned incinerators (75%) were in African American neighborhoods. Working with residents, Bullard and others at the Texas Southern University helped file a lawsuit to stop the landfill from opening. *Bean v. Southwestern Management Corp*. was the first lawsuit in the United States that charged environmental discrimination in the siting of a waste management facility. After several years in court it was ultimately unsuccessful, however, it helped set a precedent in using the Civil Rights Act to allege environmental racism.

The United States Environmental Protection Agency defines environmental justice as the "fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. EPA has this goal for all communities and persons across this Nation. It will be achieved when everyone enjoys the same degree of protection from environmental and health hazards and equal access to the decision-making process to have a healthy environment in which to live, learn, and work." Since the signing of Executive Order 12898 in 1994, the federal government is charged with making environmental justice part of its regular operations. The mainstreaming of environmental justice in U.S. federal policy has not been seamless, but it does present an opportunity for agencies to address inequities in exposure to environmental hazards that contribute to reduced opportunities and poor health.

Environmental justice considers the relationships between health and the environment and also the variations that exist within settings. In conclusion, environmental justice is not simply a function of disproportionate exposure to hazards but it also examines inequitable access to characteristics in the natural and physical environment that contribute positively to human health. The idea of a food desert has become common in scholarly and activist communities in showing how, due to planning and political economic processes, certain areas can lack access to full service grocery stores that offer healthy produce. Within urban environments there can be variations in access to green space that provides opportunities for recreation and contemplation. The recognition of these types of inequities has expanded traditional understandings of environmental justice to address the underlying factors that shape variations in exposure to both the positive and negative elements contributing to human health and well-being.

This article is a revision of the previous edition article by K. Marjoribanks, volume 7, pp. 4693–4697, © 2001, Elsevier Ltd.

Abstract

This article considers different educational environments (especially the classroom, school, and home), links between different environments, improving educational environments, and future directions, such as qualitative data-collection methods and personal forms of educational environment instruments.

Different Educational Environments

Psychosocial educational environment has been incorporated as several factors in Walberg's (1981) multifactor model of educational productivity. Based on an economic model of agricultural, industrial, and national productivity, this model holds that learning is a multiplicative, diminishing-returns function of student age, ability, and motivation; of quality and quantity of instruction; and of the four psychosocial environments – the home, the classroom, the peer group, and the mass media. Empirical probes of this model were made by Fraser et al. (1987) by carrying out extensive research syntheses involving the correlations of learning with the factors in the model. Also secondary analyses were conducted with National Assessment of Educational Achievement data (Walberg, 1986) and National Assessment of Educational Progress data (Fraser et al., 1986; Walberg et al., 1986). Classroom and school environments were found to be strong predictors of both achievement and attitudes even when numerous other factors in the productivity model were held constant. In the following subsections, consideration is given separately to the specific educational environments of the (1) classroom, (2) school, and (3) home.

Classroom Environment

Fraser's article on Classroom Climate (*see* Classroom Climate) in this *Encyclopedia*, together with a recent literature review of four decades of classroom-level environment research (Fraser, 2012), shows that a major thrust has been the development, validity, and use of various questionnaires. These publications review several lines of past classroom climate research, including evaluation of educational innovations, associations between student outcomes and classroom climate, and teachers' action–research attempts to improve their classroom climates.

School Environment

Earlier school environment instruments include Stern's (1970) College Characteristics Index (CCI) and Halpin and Croft's (1963) Organizational Climate Description Questionnaire (OCDQ). The Work Environment Scale (WES; Moos, 1981) was designed for use in any work milieu, but, to improve its face validity for use in schools, the word 'people' was changed to 'teachers,' 'supervisor' to 'senior staff,' and 'employee' to 'teacher' (Fisher and Fraser, 1983; Fraser et al., 1988). The WES was validated with 599 teachers in 34 primary and secondary schools in Tasmania (Docker et al., 1989).

The School-Level Environment Questionnaire (SLEQ) was designed especially to assess school teachers' perceptions of eight psychosocial dimensions of the environment of the school (Fisher and Fraser, 1991; Rentoul and Fraser, 1983). Two scales measure Moos's (1974) Relationship Dimensions (Student Support and Affiliation), one measures Personal Development Dimensions (Professional Interest), and five measure System Maintenance and System Change Dimensions (Staff Freedom, Participatory Decision Making, Innovation, Resource Adequacy, and Work Pressure). Using both exploratory and confirmatory factor analyses with data from 1106 teachers from 59 elementary schools in southwestern USA, Johnson and Stevens (2001) evolved a 35-item five-scale version of the SLEQ with sound psychometric properties. In South Africa, Aldridge et al. (2006) modified the SLEQ to make it suitable for use among teachers who were implementing outcomes-based education (OBE). With a sample of 403 teachers in 54 schools, they validated a questionnaire that combined modified versions of SLEQ scales with two new scales created by the researchers (Parental Involvement and Familiarity with OBE).

In Taiwan and based partly on the SLEQ, Huang and Fraser (2009) used the Science Teachers' School Environment Questionnaire (STSEQ) to assess the dimensions of Teacher–Student Relations, Collegiality, Principal Leadership, Professional Interest, Gender Equity, Staff Freedom, Innovation, Resources and Equipment, and Work Pressure among 300 female and 518 male science teachers from secondary schools. Sex differences in perceptions were reported for several scales even after controlling for teachers' background and school characteristics.

When Docker et al. (1989) used the WES with a sample of 599 teachers in investigating differences between the environments of various school types, reasonable similarity was found for preferred environment scales, but teachers' perceptions of their actual school environments varied markedly in that the climate in primary schools was more favorable than the environment of high schools for most scales. Similarly, when Fisher and Fraser (1991) used the SLEQ with 109 teachers in 10 schools, the most striking finding was that the climate in primary schools emerged as more favorable than the environment of high schools on most SLEQ scales.

In a study of the school-level environment of Catholic schools, Dorman et al. (1997) developed a school environment instrument that included modified versions of five SLEQ scales, but which added the two new scales of Empowerment (the extent to which teachers are empowered and encouraged to be involved in decision-making processes) and Mission Consensus (the extent to which consensus exists within the staff with regard to the overarching goals of the school). This instrument was used in studies of differences in the school environment of Catholic and government schools (Dorman and Fraser, 1996) and of associations between school environment and classroom environment (Dorman et al., 1997). For a sample of 208 science and religion teachers from 32 schools, Catholic school teachers saw their schools as more empowering and higher on Mission Consensus than government school teachers.

Home Environment

Generally it is agreed that school outcomes will be enhanced when home and school environments are in harmony with each other. However, relative to the voluminous research on school and classroom environments, much less research has considered the home environment, especially the joint and confounding influences of the school and the home on student outcomes. The famous Coleman et al. (1966) report drew attention to the way in which the contributions of the school and the home environments to variance in student outcomes are confounded. Kellaghan et al. (1993) clearly established the potency of positive home–school partnerships in improving student outcomes. When Allen and Fraser (2007) investigated both primary-school students' and their parents' perceptions of the classroom learning environment, it was found that both students and parents preferred a more positive learning environment, but that effect sizes for actual–preferred differences were much larger for parents than for students. At the kindergarten level, Robinson and Fraser (in press) reported that parents perceived more favorable actual environments than students, but students preferred more favorable environments than parents.

When schools are more involved with their communities and when teachers and parents see and talk more often with one another, they are more likely to know about one another's needs and are better able to work in tandem to promote the learning and welfare of students. Therefore, educational outcomes can often be improved if schools become more involved in the lives of their local communities (Berliner and Biddle, 1995). Parents have been found to have significant and positive influences on children's verbal ability, language, school-related knowledge and skills, and achievement in school subjects, especially when integrated into a network of community support (Kellaghan et al., 1993).

Links between Different Educational Environments

Although most individual studies of educational environments in the past have tended to focus on a single environment, there is potential in simultaneously considering the links between, and the joint influence of, two or more of the environments in Walberg's model of educational productivity. For example, Marjoribanks (1991, 1999) showed how the environments of the home and school interact to codetermine school achievement, and Moos (1991) illustrated links between school, home, and parents' work environments.

Several studies have investigated whether the nature of the school-level environment influences or transmits to what goes on in classrooms (i.e., the classroom-level environment). In South Africa, Aldridge et al. (2011) used a school environment instrument based on the SLEQ with 50 secondary-school science teachers from 50 different schools, together with a classroom environment questionnaire with the 2638 grade 8 students in the 50 classes of these 50 teachers. Overall, the school environment did not have a strong influence on what happens in classrooms. Other researchers who have investigated associations between school-level and classroom-level environments include Fraser and Rentoul (1982) and Fisher et al. (1995). When Dorman et al. (1997) administered a classroom environment instrument to 2211 students in 104 classes and a school environment instrument to the 208 teachers of these classes, only weak associations between classroom environment and school environment were found. Although school rhetoric often would suggest that the school ethos would be transmitted to the classroom level, it appears that classrooms are somewhat insulated from the school as a whole.

Fraser and Kahle (2007) simultaneously explored the influence of three of the environmental productivity factors in Walberg's model – namely, the school/class environment, the home environment, and the peer-group environment on students' cognitive and affective outcomes. Using secondary analysis of a large database from a Statewide Systemic Initiative (SSI) in the USA, the effects of these three types of environments on student outcomes were examined. Over 3 years, nearly 7000 students in 392 middle-school science and mathematics classes in 200 different schools responded to a questionnaire that assessed class, home, and peer environments, student attitudes, and achievement. Rasch analyses allowed comparison across student cohorts and across schools. Although all three environments accounted for statistically significant amounts of unique variance in student attitudes, only the class environment (defined in terms of the frequency of use of standards-based teaching practices) accounted for statistically significant amounts of unique variance in student achievement scores. Overall, this study reinforced the importance of extending research on school/classroom learning environments also to include the learning environments of the home and the peer group.

Improving Educational Environments

Although much research has been conducted on educational environments, less has been done to help teachers to improve the environments of their own classrooms or schools. However, Aldridge et al. (2012) have described how feedback information based on student or teacher perceptions can be employed as a basis for reflection upon, discussion of, and systematic attempts to improve classroom and school environments. Fraser and Fisher (1986) recommend five steps: (1)

assessment (students or teacher respond to both the preferred and actual forms of an environment questionnaire); (2) *feedback* (teachers are provided with feedback information derived from responses in the form of profiles representing the means of actual and preferred environment scores); (3) *reflection and discussion* (teachers engage in private reflection and informal discussion about the profiles in order to decide whether to attempt to change the environment in terms of some of the dimensions); (4) *intervention* (teachers introduce an intervention in an attempt to change the school or classroom environment); and (5) *reassessment* (the actual form of the scales is re-administered at the end of the intervention to see whether teachers/students are perceiving their school/classroom environments differently from before).

Fraser et al. (1988) used the WES as part of teacher development activities and reported a case study of a successful school change attempt in a primary school with a staff of 24 teachers. The SLEQ (Fisher and Fraser, 1991) was used in similar school improvement studies using the same basic strategy in a primary school with 15 teachers. After an intervention had been implemented for approximately 10 weeks, it was found that sizable changes had occurred in two of the targeted areas (of about two-thirds of a standard deviation and about half a standard deviation, respectively).

Future Directions

Qualitative Data-Collection Methods

Despite the considerable insights that have been generated through using educational-environment questionnaires that assess participants' perceptions, educators often feel the need to supplement these with qualitative and interpretive methods of data gathering. Furthermore, there are merits in moving beyond choosing between quantitative *or* qualitative methods, to combining quantitative *and* qualitative methods (Fraser and Tobin, 1991; Tobin and Fraser, 1998). In a mixed-methods study of learning environments in Taiwan and Australia, Aldridge et al. (1999) combined the use of a classroom environment questionnaire with classroom observations and interviews with students and teachers. The authors constructed narratives about what was going on in science classrooms in Taiwan and Australia, as well as identifying emergent themes. Overall, the qualitative information complemented the quantitative information and clarified patterns within the two countries and differences between them. Tobin et al. (1990) reported a study which focused on the goal of higher-level cognitive learning and which involved a team of six researchers intensively investigating the grade 10 science classes of two teachers over a 10-week period. Quantitative information from questionnaires assessing students' perceptions of classroom psychosocial environment was consistent with the observers' field records of the patterns of learning activities and engagement in each classroom.

Personal Forms of Educational Environment Instruments

Potentially there is a major problem with many existing educational environment instruments when they are used to identify differences between subgroups within an environment (e.g., males and females) or in the construction of case studies of individuals. The problem is that items are worded in such a way that they elicit an individual's perceptions of the environment as a whole, as distinct from that individual's perceptions of his/her own role within the environment. For example, items in the traditional class form might seek students' opinions about whether 'the work of the class is difficult.' In contrast, a personal form of the same items would seek opinions about whether 'I find the work of the class difficult.' Confounding could have arisen in past studies which employed the class form because, for example, males could find a class less difficult than females, yet males and females still could agree when asked for their opinions about the class as a whole. This distinction between personal and class forms is consistent with Stern et al.'s (1956) terms of 'private' beta press, the idiosyncratic view that each person has of the environment, and 'consensual' beta press, the shared view that members of a group hold of the environment.

When Fraser et al. (1995) developed and validated parallel class and personal forms of both an actual and preferred version of the Science Laboratory Environment Inventory, analyses confirmed that the personal form had a similar factor structure and comparable statistical characteristics to the class form. Also students' scores on the class form were found to be systematically more favorable than their scores on the personal form, perhaps suggesting that students have a more detached view of the environment as it applies to the class as a whole. As hypothesized, gender differences in perceptions were somewhat larger on the personal form than on the class form. Although a study of associations between student outcomes and their perceptions of the science laboratory environment revealed that the magnitudes of associations were comparable for class and personal forms, Fraser and McRobbie (1995) used commonality analyses to show that each form accounted for appreciable amounts of outcome variance which was independent of that explained by the other form. This finding justifies the decision to evolve separate class and personal forms because they appear to measure different, albeit overlapping, aspects of an educational environment.

Abstract

This article provides an overview of selected topics in the complex discipline of epidemiology. The aim is to focus the reader's attention to key points of epidemiology, such as definition and scope of epidemiology, criteria for causal inference, measures for morbidity and mortality, study designs, and measures of potential for prevention. Sample calculations help for a better understanding of the presented measures.

What Is Epidemiology?

Epidemiology is the scientific discipline that investigates the distribution of health phenomena (e.g., certain diseases, smoking, health behavior) in defined populations as well as factors that influence this distribution. Therefore, its premise addresses the search for predispositions and causal mechanisms for health phenomena in populations. Causal mechanisms may include a broad spectrum of biological, environmental, social, or individual factors. Epidemiology not only investigates specific factors, but also their sometimes highly complex interplay in the etiology of a certain disease. A prominent definition of epidemiology was given by Porta (2008), who defined epidemiology as "the study of the occurrence and distribution of health-related states or events in specified populations, including the study of determinants influencing such states, and the application of this knowledge to control the health problems" (Porta, 2008). In addition to the description of epidemiology given above, this definition additionally cites as an important component of the application of epidemiological knowledge in the broad field of public health.

The Scope of Epidemiology

If we want to describe the scope of epidemiology in more detail, several objectives can be addressed (see Gordis, 2009; Friis and Sellers, 2014; Tsuang et al., 2011):

1. The identification of the etiology or cause of health problems as well as the disease-relevant risk factors, that is, factors that increase a person's risk of developing the health problem. Once a factor has been shown to be a risk factor for a disease, the question of causality has to be addressed. Is the risk factor a causal risk factor, or, whenever the risk factor is modified, does this have an influence on the incidence of a disease (see terminology proposed by Kraemer et al., 1997)?
2. The investigation of the extent and burden of health problems in the community in terms of mortality and nonfatal consequences (e.g., disability associated with diseases, direct and indirect costs). This question is critical for decision making in health policy in order to improve, plan, organize, and provide health services.
3. The investigation of the natural history of diseases and health problems in terms of onset, course, and outcome.
4. The evaluation of the performance and effectiveness of existing health services. Do they cover needs in the community?

We can further divide the discipline of epidemiology into two major subdisciplines: descriptive epidemiology and analytic epidemiology (see Friis and Sellers, 2014). Descriptive epidemiology predominantly addresses the description of health phenomena in populations, their natural course, and the evaluation of health services. Analytic epidemiology deals with the extremely important question of risk factors and causality. Descriptive studies generally precede analytic studies, i.e., they identify the distribution of health problems, while analytic studies address the causes of the problems.

Measures of Morbidity

We have learned so far that the scope of epidemiology includes the description of health phenomena in populations. For this, several measures are used to describe the size of health problems. As basic measures, prevalence, incidence, mortality, and lethality will be defined in this section.

Prevalence

Prevalence is defined as the number of affected persons present in an at-risk population at a specific time or for a specific time period related to the total number of persons in that population at (for) the same time (period). This means that prevalence in fact describes a certain proportion or rate. The prevalence rate describes the proportion of the at-risk population that is affected by the disease of interest at the defined time (period).

For example, if we are interested in evaluating the prevalence rate of anxiety disorders in an at-risk population at a specific time (e.g., during the 12 months before an interview), we might use interviews to assess first the number of individuals affected by anxiety disorders defined according to the Diagnostic and Statistical Manual of Mental Disorders (DSM)-IV in that population. This number becomes the nominator for the prevalence rate. The denominator is the number of individuals in the at-risk population at this time. It

 http://dx.doi.org/10.1016/B978-0-08-097086-8.21028-3

is important to specify prevalence rates according to the time frame under consideration. For this, the term prevalence is further specified as point prevalence, period prevalence, and lifetime prevalence.

Point prevalence describes the prevalence rate of the disease of interest at a certain point in time (e.g., on a specific day).

Period prevalence describes the prevalence rate of the disease of interest in a chosen time period (e.g., within 12 months: a 12-month prevalence). It is important to point out that, for the determination of the period prevalence rate, it does not matter whether individuals developed the disease during this time period or whether they remitted or even died. All individuals affected by the disease during the time period count for the nominator.

Lifetime prevalence describes the proportion of individuals in the at-risk population that have been affected by the disease of interest at some point in their life up to the time of the assessment.

In general, prevalence rates are presented as a percentage of the at-risk population. Figure 1 presents a sample calculation for lifetime, 12-month prevalence, and point prevalence.

Incidence

Incidence is defined as the number of individuals in an at-risk population who for the first time in their life are affected during a specified time period related to the total number of persons in that population at the same time (period). Like prevalence, incidence describes a certain proportion or rate: the proportion of the at-risk population that for the first time is affected by the disease of interest during the defined time (period). For example, if we are interested in evaluating the incidence rate of anxiety disorders in an at-risk population during a specific time period (e.g., during the 12 months prior to the interview), we might first use interviews to assess the number of subjects who for the first time were affected by anxiety disorders (defined according to the DSM-V) in that population during this time period (i.e., they have never been affected before). This number becomes the nominator for the incidence rate. The denominator is the number of individuals in the at-risk population during this time period (e.g., all individuals who could have developed the disorder under consideration). Comparable to prevalence, incidence can be specified according to the time period under consideration. *Period incidence* describes the incidence rate for a certain time interval (e.g., 12-month incidence) while lifetime incidence (or cumulated lifetime incidence) describes the incidence rate for the whole life period up to the assessment (which then equals the lifetime prevalence rate). What is the difference between incidence and prevalence? While in the prevalence rate the nominator includes all individuals affected by the disorder of interest (irrespective of whether they were already affected before the time period under investigation), the nominator of the incidence rate includes only 'new' cases. Further, the denominator of the incidence rate includes only individuals that had not been previously affected by the disease, e.g., individuals with a history of the disease are excluded from the at-risk population. Figure 2 gives a sample calculation for 12-month incidence and lifetime incidence.

Mortality

Mortality expressed in quantitative terms (mortality rate) is the total number of deaths within a defined time period related to the number of individuals in the population within this period. Mortality is often specified for specific populations or specific

- **Determination of point prevalence in 12/2005 (number of cases based on population *n* = 100)**
  - **Point prevalence = 6/100 = 6%**
- **Determination of 12-month prevalence from 12/2004 to 12/2005 (number of cases based on population *n* = 100)**
  - **12-month prevalence = 8/100 = 8%**
- **Determination of lifetime prevalence (number of cases based on population *n* = 100)**
  - **Lifetime prevalence = 11/100 = 11%**

Figure 1 Sample calculation of point prevalence, 12-month prevalence, lifetime prevalence in a fictitious example.

– **Determination of 12-month incidence from 12/2004 to 12/2005 (number of cases based on population)**
  - **12-month incidence: 3/92 (population *n* = 92; exclusion of 8 cases, that ever had the disease until 12/2004)**
– **Determination of lifetime incidence until 12/2005 (number of cases based on population *n* = 100)**
  - **Lifetime incidence: 11/100**

Figure 2 Sample calculation of incidence rates from different time periods in a fictitious example.

causes. Thus, the mortality rate for all causes refers to deaths from all causes in a specific time period, while cause-specific mortality rates refer to deaths from specific causes (e.g., from heart attacks) in a specific time period. Note that the denominator in both rates consists of the number of individuals in the population during this time period. Mortality also can be expressed for specific populations (e.g., men, women, infants up to 1 year, children up to 5 years). Thus, *infant mortality* (or the infant mortality rate) measures the risk of dying during the first year of life among all infants born alive.

Lethality

Lethality in contrast to mortality describes how many individuals diagnosed as having a certain disease die within a specific time period related to all individuals with the same diagnosis during this time period. Here, the denominator includes only individuals affected by the disease of interest and not the entire population (as in the mortality rate). For a sample calculation see Box 1.

Epidemiology, Risk Factor, and Causal Inference

As discussed at the beginning of this article, the search for causes of health problems is one of the major domains of epidemiology. Schwartz and Susser (2006a,b) identified the risk-factor paradigm as the basic paradigm in epidemiologists' search for the causes of diseases.

Using the risk-factor paradigm, epidemiologists search for factors (e.g., certain exposures) that increase the risk of a certain disease in individuals who have been exposed to these factors in comparison with individuals who have not been exposed. Risk means here the probability of developing a disease, but does not imply a deterministic association. Likewise, risk factors may or may not be sufficient or necessary for the development of the outcome under consideration. According to Kraemer et al. (1997), a risk factor can be defined as "a measurable characterization of each subject in a specified population that precedes the outcome of interest and which can be used to divide the population into 2 groups (the high-risk and the low-risk-group)" (Kraemer et al., 1997: p. 338). For a factor to be called a 'risk factor,' a statistically significant association between the factor and outcome under consideration must be shown. What is important is that a risk factor precedes the outcome and must show a significant relationship with the development of the outcome (e.g., with a health problem or disease). Next, it is important to distinguish between a risk factor and the cause of a disease. According to the concept of Kraemer et al. (1997), a risk factor must precede the outcome under consideration. This is also a critical component for the definition of cause, but not a sufficient one. The group around Kraemer suggests distinguishing between 'risk factor' and 'causal risk factor.' Here, a 'causal risk factor' meets all the criteria required for a 'risk factor,' but additionally, it must be shown that a manipulation of this factor changes the outcome. Note that here the term 'causal risk factor' and not the term 'cause' is used; this is because, according to Kraemer et al. (1997), the term 'cause' often inappropriately implies that the condition is a necessary and sufficient condition for the outcome of interest.

Box 1 Sample calculation of lethality

Assume 20 deaths among 100 individuals who have developed a heart disease throughout their life. Lethality rate here would be 20/100 = 20%.

Another approach goes back to the so called Hill criteria (1965). Hill (1965) suggested criteria that should be fulfilled before interpreting an established exposure–outcome association as a causal association (or, that the exposure causes the outcome). The Hill criteria are presented in **Table 1**.

These criteria were the starting point for the discussion and modification of criteria encouraging the interpretation that an exposure plays a causal role in an outcome (i.e., in a disease) (see Schwartz and Susser, 2006a,b; Rothman and Greenland, 2005). It is important in using this approach that causality cannot be tested empirically in establishing the causal role of a risk factor, but, rather, requires evidence and consistent results from different approaches and designs. The criteria give an orientation or guidelines for a conclusion about causality, but the conclusion itself depends on a judgment based on the existing evidence.

Epidemiological Study Designs

There are several study designs that can answer epidemiological questions. The design of a study determines on the one hand its limitations and threats to validity (inherent in every study design) and the precision and validity of its findings on the other. In the following section, the basic study designs in epidemiology will be presented. A discussion of the details of each study design and of their combinations is beyond the scope of this article. For this, the reader is referred to Susser et al. (2006), Gordis (2009), Friis and Sellers (2014), Rothman et al. (2008), and Twisk (2013).

Table 1 Criteria for evidence of causal association

Criterion	*Description*
Strength of association	The stronger the association, the more likely is a causal effect
Consistency of association	Similar associations have repeatedly been found by different people, in different places, circumstances, and times (replication)
Specificity of association	An exposure is associated only with one specific health outcome and not with others
Temporality of association	There is a clear temporal association between exposure (primary) and health outcome (secondary)
Biological gradient or dose–response	Higher exposure should be associated to a higher risk
(Biological) plausibility	Given the current (biological) knowledge the causation should be reasonable
Coherence	The observed association should not be inconsistent with or in contrary to existing knowledge
Experiment	An effect is more likely to be causal if it is based on the results of an experimental design
Analogy	An association between a comparable exposition or health outcome has already been documented

Source: Hill, S.B., 1965. The environment and disease: association or causation? Bulletin of the World Health Organization 83, 796–798.

As proposed by Friis and Sellers (1999), epidemiological study designs can be discussed on the basis of two factors: (1) Manipulation of the study factor (M), i.e., that the exposure of interest is controlled by the investigator, and (2) randomization of the study subjects (R), i.e., the random assignment of the study individuals to different exposure conditions. The involvement of these two factors result in three different study designs: experimental (M and R are involved), quasi-experimental (M but not R is involved), and observational studies (neither M nor R is involved).

Experimental and Quasi-Experimental Approaches

In an *experimental study*, the investigator both manipulates the study factor (e.g., certain exposures) and randomly assigns subjects to the exposure conditions. One common experimental design is the randomized controlled trial; here, the study subjects are randomly assigned to the different conditions of the study intervention (e.g., a new therapy vs treatment as usual) in order to evaluate and compare the effects of the interventions on a modification in health status (e.g., to evaluate whether a new therapy has better effects than treatment as usual). In a *quasi-experimental study*, the study factor is manipulated by the investigator but subjects are not randomly assigned to the study conditions.

The strengths of the experimental approach include their potential for high internal validity of the findings. Limitations clearly include its low external validity (e.g., generalizability of the findings to other subjects and settings). Likewise, the vast majority of assumed factors that may be causal in the development of a disease can never be examined experimentally for the whole development phase of the disease.

Observational Approach

Although experimental and quasi-experimental studies seem to be the best approaches to maximize internal validity, it is not possible to realize them for every question of interest (e.g., causal factors in the development of a disease). Accordingly, most epidemiological research regarding causal factors in disease development is related to observational studies. Observational studies (no randomization, no control of the exposure of interest) observe individuals in order to evaluate whether an association exists between a certain exposure and the health problem of interest. This study approach is clearly more vulnerable to the effect of bias than experimental approaches and therefore internal validity is more threatened. This problem, however, may at least be minimized by the choice of a good study design. Observational studies can be used to answer research questions of both descriptive and analytic epidemiology. Descriptive studies assess information that describes the health phenomenon of interest in a selected population. Analytic studies observe exposure and the health outcome of interest and test hypotheses about the association between these factors. Once associations have been found, the search for a causal relationship can go further (see above). Observational study designs that are most often used in epidemiology include cross-sectional

studies, case–control studies, and longitudinal (cohort) studies.

Cross-Sectional Study

The cross-sectional study (also called prevalence study) is characterized by a single observation. Information about present or past exposure and outcome of interest is collected for a defined population and at a specific point in time. This study design can provide information about the distribution of health phenomena in specific populations (e.g., prevalence rates in a certain country, men, women, specific age groups). Thus, it is a good design for the evaluation of the size of health problems in terms of prevalence rates. When evaluating the association between a certain exposure and an outcome of interest, the study population is normally divided into two groups: individuals who have been exposed and individuals who have not been exposed. For the same individual, health status is collected and the association between exposure and health outcome is evaluated. The major limitation of the cross-sectional design is that it is weak in detecting potential causal associations between exposure and outcome, because it is often not possible to determine a clear temporal association between exposure and outcome of interest. Another limitation includes the use of prevalence rates in the evaluation of the association. Cases of prevalence rates may not be representative of all individuals who develop the health problem of interest (they are only included in the incidence rates) and study findings therefore may not be generalizable. The strengths of this study design include a short study period and the inclusion of large representative populations (allowing maximization of external validity).

An example of a cross-sectional study is presented in Box 2.

Longitudinal (Cohort) Study

In contrast to the cross-sectional study design, the longitudinal study design is characterized by observing study individuals over a length of time. Longitudinal studies can be further grouped into prospective versus retrospective longitudinal studies. In a prospective longitudinal study design, an investigator observes a group of individuals (the study cohort) by following them forward over a certain period of time. Across the study period, incidence rates for the health outcome of interest are assessed in both groups. This can be done in one or several follow-up assessments. The temporal association between exposure and risk (incidence) for the outcome can then be determined. For a study sample see Box 3.

The retrospective longitudinal study design is characterized by the use of historical (that means previously collected) information about the exposure condition and the inclusion of incidence rates between exposure date and study date. It is important to note that the study design does not differ: in both prospective and retrospective longitudinal designs we compare incidence rates (risk) of exposed individuals with incidence rates of unexposed individuals.

The longitudinal study design is a powerful study design for the evaluation of risk factors for health problems. Using this design, the temporal relationship between exposure and outcome is given and all people at risk are observed. This clearly maximizes the internal validity of the findings. Nevertheless, potential confounding bias (see Box 4) is always inherent in this study type (since individuals are not randomly assigned to the different exposure conditions). Another limitation is that the design is not optimal for rare diseases and diseases that develop slowly over time. Rare and slowly developing diseases would demand an immense number of study participants plus a very long follow-up period. Both are

Box 2 Example of a cross-sectional study: The National Comorbidity Survey Replication Adolescent Supplement Study

The National Comorbidity Survey Replication Adolescent Supplement is a United States national representative epidemiological survey of 10 123 adolescents aged 13 to 18 years in the United States. For the study, all participants have been assessed (interviews, questions) once within one study period fielded in 2001–2004. The scope of the study was to provide estimates of prevalence, correlates, and patterns of service use for DSM-IV mental disorders among US adolescents. Mental disorders were assessed according to DSM-IV using a modified version of the World Health Organization Composite International Diagnostic Interview (see Merikangas et al., 2009).

Box 3 Example for a prospective longitudinal study: The Early Development Stages of Psychopathology Study

The prospective longitudinal Early Developmental Stages of Psychopathology Study assessed DSM-IV mental disorders and associated risk factors in a representative sample of 3021 adolescents and young adults aged 14–24 years at baseline (T0) in Munich, Germany. The baseline assessment took place at 1995. The study also included three follow-up surveys (T1, T2, and T3 in 1997, 1999, and 2005), a family history component (T0, T2, and T3), and parent surveys (T1 and T3) (see Lieb et al., 2000; Zimmermann et al., 2008).

Box 4 What is confounding?

Confounding is a central methodological issue in nonexperimental study designs. To explain what a confounding factor is, let us start with a simple example. Suppose that we observe a positive association between the exposure 'anxiety during adolescence' and the outcome 'depression in later life.' Perhaps we are now tempted to call this a 'true' association and to infer a causal relationship between adolescence anxiety and depression in later life. This 'true' association, however, could also be a 'false' one. Suppose that another variable, e.g., the experience of early traumatic events, is associated with both, the exposure (here: adolescence anxiety) and the outcome (here: depression in later life). Suppose further that if we would account for this variable, the association between exposure and outcome of interest would disappear or become smaller. In this scenario, all or part of the association could be explained by such a so-called confounding variable. It is obvious that in this scenario failure to account for confounding can lead to biased findings in terms of spurious associations. To avoid such spurious associations, epidemiologists always have to take into account potential confounding variables that may bias their findings.

theoretically possible, but not always practicable under given research conditions.

Case–Control Study

Another often used study design is the case–control study. This study design divides the participants into two groups at the beginning of the study: those who already have the disease (cases) and those who have not (yet) developed the disease of interest (controls). Then information regarding the exposure of interest is collected in both groups. Associations between exposure and disease status can then be evaluated. The advantage of case–control studies is that they can use small group sizes and are therefore cheaper to conduct than longitudinal studies. Limitations include potential confounding bias and the retrospective assessment of exposure, which may be affected by recall bias. These facts may threaten internal validity when evaluating temporal associations between exposure and the outcome of interest. Potential bias in the selection of cases and controls may additionally threaten external validity.

Measures of Association

The above-described study designs (case–control studies, longitudinal studies) allow the collection of information about exposure condition and the health outcome of interest. If we want to determine whether a certain exposure is associated with a certain outcome, we have to answer the question of whether individuals who are exposed have a higher risk of developing the outcome of interest than unexposed individuals. When the term risk is used as an equivalent for incidence rate, we want to evaluate whether exposed individuals show higher incidence rates than unexposed people. We see at first glance that cross-sectional and case–control studies are critical in determining such temporal associations, since they do not assess incidence rates. Measures of associations that can be calculated on the basis of incidence rates include *relative risk* (*RR*) and *odds ratio* (*OR*). OR additionally can be calculated only when prevalence rate are available.

Relative Risk (Risk Ratio)

The RR can be defined as the ratio of the risk of the health phenomenon (e.g., a disease) of interest among the exposed individuals to the risk among unexposed individuals. In epidemiology, risk is calculated by the incidence rate. In other words, RR can be calculated by comparing the probability of the health problem developing in exposed individuals with the probability in unexposed individuals. A sample calculation is shown in Box 5.

The RR quantifies the strength of the association between exposure and outcome and can be equal to one, greater than one, or less than one. These values can be interpreted as follows (see Gordis, 2009):

1. If RR = 1, risk in exposed individuals is equal to the risk in nonexposed individuals, i.e., no association.
2. If RR > 1, risk in exposed individuals is greater than the risk in unexposed individuals (positive association assuming statistical significance).
3. If RR < 1, risk in exposed individuals is lower than the risk in unexposed individuals (negative association assuming statistical significance).

As we have learned in the section on study designs, only longitudinal cohort studies allow for the direct assessment of incidence rates. RR can therefore not be calculated in cross-sectional studies and case–control studies.

Box 5 Sample calculation for the relative risk

Suppose that 30 of 100 individuals who have been exposed to an early traumatic event develop depression – this shows a risk (incidence rate) of 0.3. Fifteen of 100 individuals who have not been exposed to traumatic events develop depression. The risk to develop depression is (incidence rate) is 0.15. The RR is now calculated by the risk of the exposed group compared to the risk of the unexposed group (0.3/0.15 = 2.0). Hence, the risk of developing depression of the exposed group is twice as high in comparison to the risk of the unexposed group: RR = 2.0.

Odds Ratio

In contrast to the RR, the OR is defined as the ratio of two odds (instead of two risks). Taking the perspective of a longitudinal study, the OR is the ratio of the odds of the exposed individuals to the odds of the unexposed individuals. Here, the odds of the outcome are defined as the ratio of the probability that the outcome occurs to the probability the outcome does not occur. When using incidence rates from longitudinal studies the 'probability that the outcomes occurs' is equal to the incidence rate; 'the probability that the outcome does not occur' is then one minus the incidence rate. A sample calculation is presented in Box 6.

Like the RR, the OR is a quantitative measure of association. In longitudinal studies, both measures can be calculated. The advantage of the OR is that it can also be calculated in cross-sectional and case–control studies – that means that it can be determined as a measure of the association between exposure and outcome also in these study types. When we take, for example, the perspective of a case–control study, it is possible

Box 6 Sample calculation of odds ratio

Suppose that 30 of 100 individuals who have been exposed to a traumatic event develop depression. They have a probability of 0.3 to develop depression and a probability of 0.7 not to develop depression. Here, the odds is 0.3/0.7 = 0.42. Of 100 individuals who have not been exposed to a traumatic event, 15 develop depression. In this group, the probability to develop depression is 0.15 and the probability not to develop depression is 0.85. Hence, the odds is 0.15/0.85 = 0.18. The OR is calculated as the ratio of the odds of the exposed group to the odds of the unexposed group: 0.42/0.18, so the OR is 2.3. Thus, the odds of developing depression of an exposed group is 2.3 times higher than the odds of the unexposed group.

to calculate the odds of having the exposure in affected individuals (cases) related to the odds of having the exposure in unaffected individuals (controls). The problem is just the other way round. The odds of the exposure is calculated as the ratio of the probability the exposure occurs (or occurred) in cases to the probability the exposure occurs in controls. The OR is a symmetrical measure for association and can be determined as a measure for exposure–outcome association in studies with and without incidence rates.

Measures of Potential for Prevention

In the last section, measures of association between exposure and outcome were presented. In this section, we focus on a further question: if we have identified a causal exposure, and if we could eliminate this exposure, what effect would such a modification have for the group of exposed individuals? And what would the effect be for the whole population? Or, if we could eliminate the exposure, what proportion of the incidence in exposed individuals or in the population could be prevented? The two major measures that describe such proportions are presented in the following section. A more detailed discussion is provided by Gordis (2009) and Greenland et al. (2008).

Attributable Risk

The attributable risk (AR, also referred to as excess fraction) tells us what proportion of the incidence of the outcome of interest can be attributed to a certain exposure. It is important to note that we are focusing here on the group of exposed individuals. We determine how much of the incidence (risk) in this group could be prevented if the exposure were prevented. The AR as a difference can be calculated by subtracting the incidence in the nonexposed group (which describes the background risk) from the incidence in the exposed group. The AR as a proportion describes this difference in relation to the incidence in the exposed group; therefore, we calculate ((incidence in the exposed group) − (incidence in the nonexposed group))/(incidence in the exposed group). A sample calculation is presented in Box 7.

Population Attributable Risk

The population attributable risk (PAR, also referred to as population attributable fraction) also refers to an indicator of the potential for prevention, but on the population level. This measure describes the proportion of the incidence rate of a certain outcome in the population (including both exposed and unexposed individuals) that could be prevented if a causal factor for this outcome could be prevented. In other words, the PAR describes the AR for the population. There are several ways to calculate the PAR. The calculation that is comparable to that of the AR first subtracts the incidence in the nonexposed group from the incidence in the total population and then relates this proportion or fraction to the incidence in the total population. If the incidence in the total population is not known, it can be calculated as ((incidence in the exposed group)(proportion of those exposed in the total population)) + ((incidence in the nonexposed group)(proportion of nonexposed individuals in the total population)). A sample calculation is presented in Box 8.

Another way to calculate the PAR includes as its components the probability p that the risk factor occurs in the total population and the RR (exposed vs nonexposed individuals). With these components, the PAR can be calculated as $\mathrm{PAR} = (p \times (\mathrm{RR} - 1))/(p \times (\mathrm{RR} - 1) + 1)$.

Box 7 Sample calculation of attributable risk

Suppose the 12-month incidence of onset of depression in individuals who have been exposed to a traumatic event is 60% and in unexposed individuals it is 20%. AR can be calculated as following: (incidence in the exposed individuals – incidence in the unexposed individuals)/incidence in the exposed individuals. For this example, $(0.6 - 0.2)/0.6 = 0.66 = 66\%$ of the incidence in the exposed individuals is attributable to the exposition to a traumatic event.

Box 8 Sample calculation of population attributable risk

Suppose the incidence of onset of depression within 1 year is 10% in the total population. In individuals who have been exposed to an early traumatic event, the incidence is 15% and in unexposed individuals, it is 5%. PAR can be calculated as following: (incidence in the total population – incidence in the unexposed group)/incidence in the total population. For this example, $(0.1 - 0.05)/0.1 = 0.5 = 50\%$ of the incidence in the total population is attributable to the exposition to early traumatic event.

Conclusions

This article aimed to provide an overview over selected topics in the complex discipline of epidemiology. The aim was to focus the reader's attention to key points of epidemiology, such as definition and scope of epidemiology, criteria for causal inference, measures for morbidity and mortality, study designs, and measures of potential for prevention. The reader hopefully has gained some insight and understanding of key areas of epidemiology.

Epigenetic Inheritance

Eva Jablonka and Marion J Lamb, Tel Aviv University, Tel Aviv, Israel

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Not all of the information that is transmitted between generations of cells and organisms is encoded in DNA sequences. Information is also transmitted through epigenetic systems, which include the non-DNA parts of chromosomes, self-sustaining metabolic loops, self-propagating protein structures, and small RNA molecules. Some of the properties of epigenetic inheritance make it very different from genetic inheritance, particularly because new epigenetic variants can arise in response to the conditions of life. Consequently, understanding epigenetic inheritance is important for medicine, agriculture, public health, and environmental conservation. It also alters views about evolution.

Introduction

'Epigenetic inheritance' is a term used to describe the transmission from generation to generation of structural and functional variations that do not depend on differences in DNA base sequences. In its broadest sense, the term can also include the transmission between generations of nongenetic variations in behavior, but its use is usually restricted to transmission in cell lineages. The inheritance of induced epigenetic changes is part of normal development, but epigenetic variants can also be transmitted from one generation of individuals to the next. Understanding epigenetic inheritance is of practical importance for medicine and agriculture, and has theoretical implications for ideas about heredity and evolution.

Definitions and Historical Background

'Epigenetics,' 'epigenetic,' and 'epigenetic inheritance' are relatively new terms, derived from the much older term 'epigenesis.' According to the ancient and influential theory of epigenesis, development involves qualitative changes in organization, with the parts of an adult animal forming gradually and sequentially from an ovum that is amorphous and unorganized. In the rival theory of preformation, which was popular in the late seventeenth and eighteenth centuries, development was assumed to entail the growth or unfolding of parts that already exist in miniature in the egg (Pinto-Correia, 1997). Since the beginning of the nineteenth century, it has been accepted that development is through epigenesis, although a subtle form of preformation was introduced toward the end of the nineteenth century, when it was recognized that although developmental changes are qualitative, they are controlled by preformed determinants whose transmission and effects ensure hereditary continuity. For several decades after the rediscovery of Mendel's laws in 1900, the new science of genetics was concerned with the way these determinants, the genes, are transmitted from one generation to the next; their role in development received little attention until the second half of the twentieth century.

The introduction of the term 'epigenetics' by the British embryologist Conrad Waddington in the late 1930s (Waddington, 1975) reflected a growing interest in the relationship between genes and development, an interest that increased as the molecular nature of the gene was unraveled. Waddington coined the term epigenetics for the study of the causal mechanisms of development; the adjective 'epigenetic' is applied to the processes through which the genetic information in a fertilized egg is expressed and used in the production of the adult form, the visible phenotype. As the study of genetics and development progressed, it became clear that different cell types usually have identical genotypes, but express different sets of genes (one important exception proved to be the cells of the immune system, where epigenetic changes involve alterations in DNA sequences). Finding out which genes are expressed and what controls when and where they are expressed became the key to understanding the functional and structural specialization of cells and tissues during development. It also became clear that once a cell is committed to a particular form or function, that determined state is often transmitted to daughter cells, even though the stimulus that originally induced its development is no longer present. Thus, once a cell is committed to becoming a liver cell, it breeds true and by division gives rise to a lineage of liver cells; similarly, skin cells will give rise to skin cells, and kidney cells to kidney cells. This stable transmission of the alternative phenotypes of cells having the same genotype became known as 'cellular heredity,' 'cell heredity,' or 'epigenetic inheritance.'

Interest in the transmission of cellular states began to grow during the mid-1970s, as the molecular mechanisms and systems that underlie the control of gene expression started to be unraveled (Holliday, 1990). Gradually it was recognized that epigenetic information is transmitted not only between generations of cells in lineages within each individual, but also through the germline and gametes to the next generation of individuals. The concept of epigenetic inheritance was therefore extended and now has both narrow and broad meanings. The narrow meaning limits it to heredity in mitotically dividing cell lineages, whereas the broader meaning includes the transmission of epigenetic information between any reproducing entities – cells, individuals, and even groups of individuals. In this article, we first describe mechanisms of epigenetic inheritance in cell lineages within organisms, and then consider the evidence for and consequences of the transmission of epigenetic variations between

generations of individuals. More details of the historical development and scope of ideas about epigenetic inheritance can be found in Jablonka and Lamb (2002, 2011).

Mechanisms of Epigenetic Inheritance

The changes that occur during the determination and differentiation of both dividing cells (such as stem cells or germ cells) and nondividing cells (such as brain cells) are established and maintained by a variety of epigenetic mechanisms, some of which enable aspects of the cell's phenotype to be transmitted to descendent cells or organisms. We have called the mechanisms that underlie such transmission 'epigenetic inheritance systems' (EISs), and initially characterized three broad categories: steady-state systems, structural systems, and chromatin-marking systems (Jablonka and Lamb, 1995). A fourth EIS, based on the transmission of small regulatory RNAs, was recognized in the late 1990s (Jablonka and Lamb, 2005, 2010).

Steady-State Systems

Patterns of gene activity can persist in cell lineages through the operation of regulatory feedback loops. The simplest example is a gene that controls its own transcription through positive feedback. When the activity of such a gene is induced by an external stimulus, some of the gene's product binds to its own control region. This binding leads to the continued activity of the gene. In this way, gene activity that initially depended on the presence of an external inducer is maintained by self-regulation – by the continuous induction of the gene by its own product. If the concentration of the gene product is high enough and cell division is more or less equal, the gene's active state will be inherited, because the regulatory gene product will be transmitted to daughter cells as an automatic consequence of cell division. This type of self-regulation means that cells with the same DNA sequence can have different but stable patterns of cell-heritable activities, which either reflect their developmental history or are the result of stochastic switching between alternative states. Many examples of such self-perpetuating regulatory loops have been found in both animals and plants (Jablonka and Raz, 2009). In most cases, the systems are more complicated than the one just described because several genes and gene products are involved in the feedback loop, but the principle is the same.

Structural Inheritance Systems

Cells contain many complex three-dimensional structures whose assembly seems to depend on the presence of preexisting similar structures. In ways that are not fully understood, old structures are used as templates for the production of the new structures that are required for cell growth and multiplication. The best-known examples of this type of inheritance come from studies of single-celled organisms, such as the ciliated protozoan *Paramecium*. Genetically identical paramecia can show heritable differences in the patterns of cilia (tiny hairlike structures) on their cell surface, and experimentally altered patterns can be transmitted to daughter cells for hundreds of cell generations (Beisson, 2008). Although this type of inheritance is particularly conspicuous and stable in ciliated protozoa, structural inheritance is probably universal, since all cells rely on preexisting structures when they produce new ones. The growth of many cell membranes, for example, requires the presence of preexisting membrane (Cavalier-Smith, 2004). The templating properties of some aberrant proteins are believed to underlie the transmission of mad cow disease (bovine spongiform encephalopathy (BSE)) and several other neurodegenerative diseases of humans. In these diseases, misfolded proteins – prions – multiply by inducing function-affecting changes in the conformation of normal proteins. Not all prions are pathological, however. There are reasons for thinking that transmissible, self-propagating, prionlike proteins are involved in regular functions such as memory storage and innate immune responses (Soto, 2012). The best evidence for a functional role for prions comes from yeast, where switching between heritable prion and nonprion forms of certain proteins involved in DNA information processing enables cells to adapt rapidly to changed conditions. In a study of about 700 wild yeast strains, one-third were found to carry prions, many of which affected the phenotype in ways that in some conditions could be adaptive (Halfmann et al., 2012).

Chromatin-Marking Systems

Chromatin, the substance of chromosomes, is a combination of DNA, bound histone and nonhistone proteins, and RNA molecules. It is constantly being remodeled as small chemical appendages such as methyl groups are added to or removed from the nucleotides of DNA, as the amino acids in histones are modified by having chemical appendages added to or taken away from them, and as the various histone and nonhistone proteins and RNA molecules come and go from the complex. The different patterns of chromatin modifications are known as 'chromatin marks' and affect the way that DNA sequences are interpreted (Jablonka and Lamb, 2005, 2010). Epigenetic information that is contained in chromatin marks can be inherited by being carried from one cell generation to the next with replicated DNA. A good example of an inherited chromatin mark is a DNA methylation pattern. In many plants and animals, some of the cytosines in DNA are methylated. Although cytosine (C) is one of the four bases whose sequences encode genetic information, the presence of a methyl group (^{m}C) does not affect its coding properties. However, cytosine methylation within or around a gene often determines whether or not the gene is active, and how easy it is to activate: usually low levels of methylation in noncoding regions are associated with potential activity, while high levels are associated with inactivity. Changes in methylation patterns occur during growth and development, so the same DNA sequence can have several different methylation patterns, each reflecting a different functional state, and each is inherited stably through many cell divisions. One of the mechanisms through which methylation marks are transmitted to daughter cells depends on the way a cytosine in one strand of the DNA double helix is always paired with a guanine (G) in the other. Methylation usually occurs symmetrically on the two strands, most commonly in CG

doublets in which ^{m}C G is paired with G ^{m}C. Following DNA replication, in which the two parental DNA strands separate and are used as templates for building complementary daughter strands, the previously methylated sites remain methylated on the parental strand but are unmethylated on the newly synthesized daughter strand. However, special enzymes recognize the asymmetrical, half-methylated sites, and preferentially methylate the cytosines of the new strand (Holliday, 1990). Thus, because of the mirror symmetry of CG sites and the semiconservative nature of DNA replication, the specific pattern of methylation is reproduced at every cell division. In recent years, new types of DNA modification and additional cellular factors that are involved in methylation and demethylation have been discovered, and it has become clear that interactions between DNA methylation and the other heritable components of chromatin are important, so the overall picture of methylation marking is becoming far more complex (Law and Jacobsen, 2010). Nevertheless, DNA methylation remains the best understood chromatin-marking EIS.

Histone proteins, which form a large part of chromatin, are also important in chromatin marking. Which of the histone variants are present, the position of histones relative to DNA, and the way they are changed through acetylation, methylation, or other modifications of their amino acids all have roles in epigenetic regulation, and the organization and modifications of histones can to some extent be mitotically and sometimes meiotically inherited. Although the molecular mechanisms through which this occurs are far from clear, parental histone assemblies seem to be used as blueprints for restoring similar configurations in daughter cells (Margueron and Reiberg, 2010).

Different types of chromatin marks commonly interact, with the inheritance of one type being influenced by or even dependent on another (Bonasio et al., 2010). The type of histone and nonhistone proteins that are bound to DNA, the nature of the histone modifications, and the patterns of DNA methylation are all interdependent, so understanding the establishment, maintenance, and inheritance of epigenetic marks is extremely difficult.

Small-RNA Systems

Early in the twenty-first century, it became apparent that small RNAs (sRNAs) are central to the regulation of cellular activities and also take part in the transmission of epigenetic information (Ghildiyal and Zamore, 2009). RNA interference (RNAi) – gene silencing through sRNAs – has been found in almost all eukaryotes, and prokaryotes have analogous mechanisms. There are several types of RNAi, but in all of them precursor RNA molecules derived from external sources such as viruses or experimental manipulations, or from endogenous DNA sequences, are cut into sRNAs, usually 20–30 nucleotides long. After processing, these sRNAs are loaded onto protein complexes that bring about the silencing of nucleic acid sequences that are complementary to the sRNAs. The mechanisms through which sRNA–protein complexes silence gene activity include (1) binding to complementary messenger RNA (mRNA) sequences, thereby preventing their translation or causing their degradation; (2) targeting chromosome regions with similar DNA sequences, which they silence through DNA methylation or repressive histone modifications; and (3) excising homologous sequences from chromosomal DNA. Sometimes the products of sRNA-directed mRNA degradation can trigger the transcription of more precursor sRNAs, thus forming a self-sustaining loop. In whichever way sRNA-mediated silencing is achieved, it can be inherited, and there are several (not necessarily mutually exclusive) mechanisms through which this can occur. First, sRNAs can be replicated by an RNA-dependent RNA polymerase, and these replicated RNAs can then be distributed to daughter cells during cell division. Second, when sRNA–protein complexes guide chromatin modifications, the altered chromatin marks are inherited. Third, when sRNA–protein complexes lead to the excision of DNA sequences, the new, depleted DNA is inherited through conventional DNA replication. Fourth, some sRNAs can be moved horizontally from cell to cell.

Although for descriptive purposes we have distinguished four types of systems through which epigenetic information can be transmitted in cell lineages, each category includes multiple, sometimes disparate mechanisms. Moreover, the relative importance of the various mechanisms differs among organisms, and as the sRNA systems show clearly, the four inheritance systems are often interrelated and interdependent (Olovnikov et al., 2012).

Transgenerational Epigenetic Inheritance

Studies of the mechanisms of epigenetic inheritance were initially focused on cells in the cell lineages of multicellular organisms, but subsequently it was found that single-celled organisms such as bacteria and yeasts also transmit epigenetic variations to their descendants, and that multicellular organisms sometimes transmit epigenetic variations between generations (Jablonka and Lamb, 1995). Transgenerational transmission was recognized in two ways: either as genomic imprinting, in which a gene's expression is influenced by the sex of the parent who transmitted it, or as the long-term inheritance of acquired variations over several generations.

Genomic Imprinting

During the formation of sperm and eggs, chromatin is modified. The way that it is modified in the male and female germlines differs, so, at the beginning of embryonic development, the genes transmitted by the two parents are in different epigenetic states. If these differences persist during development and have phenotypic effects, the genes are said to be 'imprinted' (Ferguson-Smith, 2011). Imprints may involve differences in methylation patterns, histone marks, and sRNAs. The effect of genomic imprinting is that the expression of some genes depends on the sex of the parent from which they were inherited (parent-of-origin effects). Normally, imprints are erased and replaced in the germline, so when a gene that was inherited from one sex is transmitted to the next generation through the opposite sex, the imprints are reversed. Imprinting is widespread in both plants and animals and is known to be necessary for normal development. Several human diseases,

including Prader–Willi, Beckwith–Wiedemann, and Angelman syndromes, are associated with imprinting impairments.

Long-Term Epigenetic Inheritance

Epigenetic inheritance that lasts for more than a single generation has been found in all of the taxa in which it has been sought, from bacteria to humans. A literature search by Jablonka and Raz (2009) identified 102 well-documented cases of transgenerational epigenetic inheritance in 42 different species. This survey and subsequent reviews of epigenetic inheritance in plants (Richards, 2011) and mammals (Daxinger and Whitelaw, 2012) leave little doubt that epigenetic variants that can be transmitted through the germline are not uncommon, that several molecular mechanisms are involved in their transmission, and that the fidelity with which they are inherited depends on many different internal and external factors.

The most extensive evidence for epigenetic inheritance undoubtedly comes from work with plants, particularly with the small self-fertilizing thale cress, *Arabidopsis thaliana*, now the most common model organism used by botanical geneticists. Work summarized by Schmitz and Ecker (2012) shows that hundreds of genomic regions can be differentially methylated, and that many methylation marks are stably inherited between generations. The spontaneous rate of production of methylation variants is more than four orders of magnitude greater than that for gene mutations, and when methylation variants are induced, some of the new phenotypes are adaptive and have a high heritability.

In animals, one of the fascinating and important aspects of the evidence for epigenetic inheritance is that it shows that, contrary to the long-held beliefs of most biologists, induced or acquired changes in morphology, physiology, and behavior can be transmitted to future generations. For example, Remy (2010) found that olfactory imprints in the nematode worm *Caenorhabditis elegans* can be inherited. Studies of the same organism have shown that even a complex trait like lifespan can be altered by histone modifiers, and that the induced change – in this case, extended longevity – can be passed to several generations of descendants (Greer et al., 2011). Daxinger and Whitelaw (2012) have summarized data showing that even in mammals, some induced changes are transmitted to subsequent generations. This has been found in the mouse, where the expression of several metastable alleles can be heritably modified by environmental factors. *Agouti viable yellow* (A^{vy}), for instance, is an allele that has a noticeable effect on fur color, but also affects the incidence of diabetes and obesity. The allele's expression is variable, and this variation is correlated with methylation and histone marks in its control region. The chromatin marks and associated strength of gene expression are inherited. Feeding pregnant females with folic acid, betaine, or other methyl donors increases the expression of the A^{vy} allele in their offspring, and this increase is transmitted to subsequent generations, albeit not very stably.

There is substantial and worrying evidence, some of which is summarized by Jirtle and Skinner (2007), that physiological and behavioral variations resulting from exposure to environmental toxins or psychological stresses can be inherited. For example, four generations of male rats whose male ancestors were exposed as fetuses to the fungicide vinclozolin, which is a potent androgen suppressor, showed a greater incidence of testis abnormalities, infertility, kidney and prostate diseases, and immune system problems. They also had different adult responses to stress administered during adolescence (Crews et al., 2012). These changes were correlated with altered DNA methylation in the male germ line, and changes in gene activity in the brain. Psychological traumas are also known to affect future generations: mice that had been separated from their mothers for a few hours each day for the first 14 days of their lives later showed various behavioral and emotional abnormalities, which were transmitted by males to their offspring. The transmitted behaviors were associated with changes in germline and brain DNA methylation, and in gene expression (Franklin et al., 2010). In humans, starvation, psychological stress, and exposure to various toxins are all known to have long-term effects on physiology and behavior, and in some cases these effects have documented or suspected epigenetic underpinnings (Thayer and Kuzawa, 2011). Evidence for transgenerational transmission in humans is limited, but using surveys and historical data, Pembrey and his colleagues concluded that both smoking and food supply can have effects that are transmitted transgenerationally through the male line (Pembrey et al., 2006; *see also* Twin Studies and Epigenetics).

Genetic and Epigenetic Inheritance Compared

The properties of genetic and epigenetic inheritance in cell lineages overlap, but certain features are more characteristic of one than the other. Most differences stem from the fact that epigenetic systems are concurrently both transmission and response systems, whereas the genetic system is specialized more for transmitting information than for responding to internal or external cues. The response function of epigenetic systems means that, unlike most genetic variations, the occurrence of new heritable epigenetic variations is not random – variations are often induced by specific developmental signals or environmental challenges, and are targeted to particular regions of the genome. Sometimes, induced epigenetic variations are adaptive, although they need not be so. Whereas changes in the DNA sequence of a gene are rare, and reversion to the original sequence is even rarer, the response function of EISs means that, under some circumstances, especially in conditions of stress, the rate of change between epigenetic variants is very high, and coordinated changes may occur in the epigenetic marks of several genes. However, although some inherited epigenetic changes differ from typical genetic changes in being targeted, inducible, frequent, reversible, and adaptive, others resemble classical genetic mutations in that they are rare, random, nonadaptive, and unlikely to revert. Because changes in DNA can sometimes be targeted and involve many loci (Shapiro, 2011), no single criterion can be used to distinguish between the properties of the genetic and epigenetic systems, and molecular investigations are necessary to unequivocally identify the epigenetic or genetic nature of heritable variation.

Implications

Recognizing the ubiquity and developmental importance of cellular epigenetic inheritance has major implications for medicine, ecology, and related disciplines (Gilbert and Epel, 2009), and also for the way that we think about heredity and evolution (Jablonka and Lamb, 2010; Jablonka, 2013). It has forced the biological and medical communities to move away from the idea that heredity is determined solely by information carried in DNA sequences. In this article, we have focused on transmission in cell lineages and through the gametes, but as we indicated earlier, in its broad sense epigenetic inheritance includes routes of information transmission that bypass the germline. It therefore includes behavioral transmission of the type revealed by Weaver and his colleagues in laboratory rats (Weaver et al., 2004). These scientists found that the mothering style of rats – how much nursing, licking, and grooming they gave their pups – affected the way in which these youngsters responded to stress when adult, and the type of mothering that the adult females gave to their own pups. Rats raised by less nurturing mothers were more sensitive to stress than those raised by more caring mothers, and the female offspring of mothers who gave deficient care themselves became less caring mothers. The differences in mothering style and responses to stress were associated with epigenetic differences in chromatin marks and the expression of certain genes in the brain. It was possible to reverse the behavior of the timid adult offspring of the less caring mothers by using chemicals that changed their chromatin marks. However, although the poor mothering style and consequent fearful adult behavior were perpetuated in families, cross-fostering experiments showed that the epigenetic differences were not transmitted through the germline: foster mothers transmitted their style of care to their adopted pups as well as their own offspring. Therefore, although epigenetic marking was involved, transmission was through the mother rats' behavior, not through epigenetic marks carried in their germ cells.

Practical Implications

The importance of all types of heritable epigenetic variations in health and disease is today widely recognized. First, it is known that many cancers are associated with cell-heritable epigenetic modifications, such as alterations in methylation patterns and other aspects of chromatin organization. Second, chronic diseases such as some types of diabetes, coronary diseases, and mental disorders have been shown to have epigenetic correlates. Third, some hereditary diseases are caused by mutated (or epimutated) imprinted genes, which show peculiar but characteristic patterns of inheritance. Fourth, diseases such as BSE and kuru are caused by prions – transmissible, infectious, and abnormally folded proteins. Fifth, it is accepted that in order to cope with pathogenic microorganisms and other parasites, the effects of their adaptive epigenetic systems have to be countered. This knowledge is being incorporated into medical practice and epidemiological research programs, and new ways of recognizing, avoiding, and curing the diseases caused by heritable epigenetic changes are being developed.

Epigenetics has provided powerful tools for innovations in medicine and agriculture. Many of the early discoveries in the field were stimulated by attempts to solve problems associated with the low success rate of reproductive technologies such as cloning. Now that greater knowledge has made it easier to manipulate epigenetic marking, this technique is more successful. In addition, the possibility of replacing diseased or damaged tissues by using cells that have been epigenetically reprogrammed to become stem cells has made regenerative medicine a likely future growth area. The potential economic benefits of exploiting the sRNA systems were obvious as soon as the RNAi system was recognized, and private and public money has been pouring into this area of research. By introducing synthetic RNAs into cells, specific genes can be heritably silenced; not only is this a powerful tool for investigating gene functions, but also it provides a novel strategy for treating human diseases and for modifying commercial plants and animals.

The importance of epigenetic inheritance for ecological and environmental issues is acknowledged by the fact that a new discipline, ecological epigenetics, is beginning to emerge (Bossdorf et al., 2008; Ledón-Rettig et al., 2013). Most biologists now realize that the changes in ecological conditions that are taking place as a result of global warming will induce changes in physiology and behavior, some of which will be heritable and lead to new adaptations and new problems. The effects of chemical environmental pollutants are also likely to have enduring consequences. Not only do many of these chemicals persist in the environment for long periods, but also some induce epigenetic changes that are heritable, so even brief exposures can have long-term detrimental effects. For example, work with rats has shown that fetal exposure to low doses of some commonly used chemical pesticides, plastics, and hydrocarbon fuels can lead to epigenetic changes in the age of puberty, and alter gonadal functions in ways that reduce fertility. Each compound caused a distinct set of alterations in DNA methylation, and the induced epigenetic effects were inherited for three generations (Manikkam et al., 2012).

Although it is rarely recognized, epigenetic inheritance also has important implications for the social sciences. Thayer and Kuzawa (2011) are among those who have suggested that some of the persistent social and health disparities between different classes or races may be consequences not only of recent socioeconomic inequalities but also of the germline transmission of epigenetic effects resulting from the experiences of earlier generations. If so – and the work cited earlier in this article suggests it is likely to be so – it will be necessary to identify, compensate, and reverse any adverse inherited epigenetic effects, as well as deal with the current causes of inequality.

A Broader Concept of Inheritance and Evolution

When epigenetic inheritance and other non-DNA inheritance systems (such as the transmission of information through behavior or language; *see* Gene-Culture Coevolution) are included in heredity, it becomes a much richer and more general concept. No longer does heredity depend solely on variations in the sequences of nucleotides in DNA. Even at the cellular level of inheritance, the production and transmission

of variations involve several different types of molecules and several mechanisms. With some of these mechanisms, such as those underlying structural inheritance and steady-state systems, there is no real equivalent of the phenotype–genotype distinction, because the developmental reconstruction of the phenotype is an integral part of the transmission mechanism (*see* Genotype and Phenotype).

With all EISs, the inheritance of acquired (induced) variation is a common and regular occurrence, with the environment being both an inducer and a selector of epigenetic variations. Epigenetic inheritance can therefore be seen as a form of 'soft inheritance.' Ernst Mayr, one of the twentieth century's most influential evolutionary biologists, described soft inheritance as "the belief in a gradual change of the genetic material itself, either by use or disuse, or by some internal progressive tendencies, or through the direct effect of the environment" (Mayr, 1998, p. 15). Because he identified inheritance with genes and DNA, Mayr asserted, "It was perhaps the greatest contribution of the young science of genetics to show that soft inheritance does not exist" (Mayr, 1998, p. 17). Throughout the second half of the twentieth century, Mayr campaigned vigorously against the inclusion of soft inheritance in evolutionary thinking, trying to consolidate a view of Darwinism that was free of any Lamarckian overtones. For him and his many followers, the only heritable changes that were important in evolution were those that occurred in DNA. Consequently, there was a delay in recognizing the significance of epigenetic inheritance, which certainly reintroduces Lamarckian notions into evolutionary theorizing (Gissis and Jablonka, 2011). Today, because epigenetic inheritance and other types of nongenetic information transmission across generations are acknowledged to be widespread, the existence of 'soft' inheritance is no longer in doubt (Bonduriansky, 2012). Biologists are accepting a more pluralistic notion of heredity.

Theoretical models that incorporate an expanded concept of heredity are showing that epigenetic inheritance can have profound effects on the rate and direction of evolution. First, spontaneous epigenetic changes occur much more frequently than genetic changes, so adaptive responses to new challenges can be rapid. Second, epigenetic variants that are repeatedly induced by persistent environmental conditions can produce phenotypic change in a population without selection. Third, even variants that are not stably transmitted can be adaptive. For example, inheriting an epigenetic defense against a pathogen for just a few generations can be a good evolutionary strategy if the type of pathogen in the environment changes frequently, and evolutionary modeling has shown that the fidelity with which epigenetic variants are transmitted should evolve to match environmental fluctuations (Jablonka and Lamb, 1995). Fourth, as well as being a source of selectable variation in their own right, operating alongside the genetic system, EISs have a very significant influence on how the frequencies of genetic variants are changed by selection. If, for instance, an allele that previously had been heritably silent and therefore invisible to selection is heritably activated, even for a few generations, then the allele's frequency in the population may change because the epigenetic modification has made it visible. New theoretical frameworks are being developed that make it possible to analyze the interactions of the genetic and epigenetic systems, and these are showing that incorporating nongenetic inheritance drastically alters predictions about the course of evolutionary change that are based solely on genetic inheritance (Day and Bonduriansky, 2011; Geoghegan and Spencer, 2012). In addition to its strong effects at the population level, epigenetic inheritance is important in the process of speciation, and contributes to novel, large-scale, adaptive changes (Jablonka and Lamb, 1995, 2010).

The broadening of the concept of heredity, and recognition that natural selection acts on several different types of heritable variation, which began in the last decades of the twentieth century, has challenged the widely accepted gene-centered neo-Darwinian version of Darwinism (*see* Darwinism; Evolution, History of). A more comprehensive and more powerful Darwinian evolutionary theory is now being constructed, one that incorporates multiple and interacting inheritance systems.

Abstract

The external environment plays a primordial role in determining gene expression, and protein production, which may in turn define a behavioral or physiological phenotype. This control occurs at both the transcriptional and translational levels and involves a wide range of mechanisms, providing a plethora of opportunities for altering the final level of functional proteins. These mechanisms all share the common feature that they do not alter the underlying genomic sequence, but they act as biological annotations to the genome. In this article we review these mechanisms, and how they are related to health. In particular the role of the three epigenetic mechanisms in controlling the glucocorticoid receptor, as well as the stress phenotype, is reviewed in detail.

The Three Principal Mechanisms of Epigenetic Regulation

DNA Methylation

Cytosine methylation is the principal epigenetic mechanism operating directly on the genomic DNA, and it is the only natural covalent DNA modification in vertebrates. Methylation occurs in mammals only on the 5′cytosine in a CpG pair, that is, on cytosines immediately followed by a guanine. Between 60 and 90% of genomic CpGs are thought to be methylated. CpG dinucleotides are not equally distributed throughout the genome, but are found in clusters, called CpG islands where they are significantly overrepresented. In the human genome there are about 29 000 CpG islands, covering about 1% of the genome. Dinucleotides within CpG islands have long been thought to be protected against methylation, while those throughout the remaining 99% of the genome are mostly methylated.

DNA methylation patterns are tissue specific. They are established during embryogenesis, and they are maintained during normal cell division (mitosis). However, during germ cell division (meiosis) both parental genomes are demethylated and during embryogenesis individual fetal methylation patterns are reestablished. This is particularly obvious in monozygotic twins born with virtually identical methylation patterns, that are different from those of their parents. Differences between the twins only develop after birth, and increase with age. In general, global methylation levels tend to decrease with age (Fraga et al., 2005). In mammalian cells, CpG methylation plays an important role in the regulation of tissue-specific gene transcription and silencing. It is also considered one of the principal interfaces between the environment and the host genome (Fraga et al., 2005; Szyf, 2011), and explains phenotypic variations in humans that are caused by the environment and have long-term programming effects.

Although methylation patterns may remain stable over long time periods, and global methylation levels from repetitive elements decrease at rates of only 0.06–0.12% per year (Bollati et al., 2009), DNA methylation is reversible either by enzymatic removal (He et al., 2011; Ito et al., 2011) or by the inhibition of maintenance of DNA methyltransferases such as DNMT1 during mitosis (**Figure 1**).

DNA 'Packaging' – Chromatin Structure and Modifications

In all eukaryotes the activity of genomic DNA is tightly regulated within the context of a nucleoprotein structure called chromatin. The fundamental unit of chromatin is the nucleosome. The nucleosome consists of an octamer of histones, including two copies of each core histone (e.g., H2A, H2B, H3, and H4) around which 146–147 base pairs of DNA are wrapped. Nucleosomes create a physical barrier to the accessibility of the underlying DNA. 'Open' or 'closed' conformations regulate fundamental DNA-template processes like transcription, DNA replication, DNA-damage repair, or DNA recombination. Chromatin can be dynamically remodeled by DNA methylation or covalent posttranslational histone modifications both of which provide a link between environmental conditions and the transcription of the genes in the remodeled area.

Posttranslational Modifications of Core Histones and Their Role in Transcriptional Regulation

The flexible N-terminal tails of the core histones protrude from the nucleosome body and are freely accessible to a growing list of histone-modifying enzymes that deposit (e.g., acetyltransferases, methyltransferases, kinases, ubiquitinases) or remove (e.g., deacetylases, demethylases, phosphatases, deubiquitinases) various covalent posttranslational modifications (PTMs). Histone PTMs are epigenetic marks playing an important role in defining the chromatin state that ultimately controls the transcriptional activity (Bannister and Kouzarides, 2011). Even though robust, they are considered

Figure 1 Schematic representation of the principal levels of epigenetic regulation. Genomic DNA is packaged in chromosomes consisting of nucleosomes with 146–147 basepairs of genomic DNA wrapped round them. The first level of epigenetic regulation is the modification of the histones that make the nucleosome. The second level of epigenetic regulation is DNA methylation, occurring on cytosines in CpG dinucleotides. After transcription, the mRNA is targeted as the third level of regulation by microRNAs. Targeting of mRNA regulates the production of protein from the mature messenger RNA.

to be more flexible than the CpG methylation marks. The link between PTMs and transcriptional activity depends essentially on the chemical nature of the covalent modification as well as the position and nature of the modified histone residue. In general, histone PTMs exert their effects via two main mechanisms: either they regulate biological processes by directly altering the overall chromatin structure or they influence the recruitment of secondary effectors that ultimately define the functional outcome of the PTMs. The combinatorial nature of the large number of available modifications and modification sites provides a 'histone code,' with specific modifications corresponding to either transcriptional repression or activation (summarized in Table 1; Figure 2).

Histone Acetylation

Histone acetylation directly influences the chromatin structure. The positive charge added by acetyl groups loosens the interactions between histones and the negatively charged DNA, resulting in a less tight packaging of the chromatin structure that renders the underlying DNA more accessible to the transcriptional machinery. Histone acetylation of lysine (K) residue side chains is performed by histone acetyltransferases and can be actively reversed by histone deacetylases (HDACs) (Yang and Seto, 2008). Histone acetylation is closely linked to DNA methylation. Cytosine methylation levels are interpreted by two families of methyl-CpG-binding proteins (Klose and Bird, 2006), the methyl-binding domain (MBD) family, and the Kaiso family. The interaction of these methylation interpreting

Table 1 The 'histone code' of common core histone modifications found in psychobiological paradigms and phenotypes

	Histone H3					*Histone H4*	*Histone H2B*
Residue	K4	K9	K27	K36	K79	K20	K5
Monomethyl			Activation		Activation	Repression	Activation
Dimethyl	Activation		Repression	Activation	Activation		
Trimethyl	Activation	Repression	Repression		Activation + Repression	Repression	Repression
Acetylation	Activation	Activation	Activation				Activation

Figure 2 Schematic representation of the nucleosome, and histone tail modifications. The nucleosome consists of four core histones: H2A, H2B, H3, and H4. Epigenetic modifications occur on the histone tails. Modifications to the Lysine (K) and Arginine (R) residues shown are Ac acetylation, Me methylation, Ub ubiquitination. The linker histone, H1, has similar modifications that are not illustrated.

Figure 3 The principal of microRNA (miRNA) synthesis and actions. In the nucleus both the miRNA and the target are transcribed. Initially pri-miRNA is produced that is processed into pre-miRNA by Drosha and subsequently exported from the nucleus by Exportin. After processing by Dicer, the mature miRNA is incorporated into the RNA-induced silencing complex (RISC) and subsequently binds to the target mature mRNA.

proteins with HDAC complexes initiates the condensation of chromatin into transcriptionally closed structures (Prokhortchouk et al., 2001).

Histone Monoubiquitination

Reversible monoubiquitination (ub1) consists of the covalent addition of a single ubiquitin peptide (76 amino acids) by the sequential catalytic activity of an ubiquitin-activating enzyme (E1), an ubiquitin conjugation enzyme (E2), and an ubiquitin ligase (E3). The monoubiquitin peptide is about two-thirds of the size of a histone and thus constitutes an additional bulk that most probably leads to a profound change in the overall nucleosome conformation, and can be either a marker for high transcriptional activity for example, on H2B, or on the contrary for transcriptional repression for example, on H2A.

Histone Methylation

Histone methyltransferases deposit and histone demethylases remove methylation marks on the side chains of more than 20 different K or arginine (R) residues. Each K residue can be mono-, di-, or trimethylated and R residues, mono- or dimethylated further increasing complexity (Bannister and Kouzarides, 2011). In contrast to histone mono-ubiquitination and acetylation, histone methylations do not induce obvious changes in the chromatin structure, although they increase the hydrophobicity of the side chains potentially creating new binding surfaces for reader proteins, influencing transcriptional activity through altered recruitment of the transcriptional machinery (Bannister and Kouzarides, 2011).

MicroRNAs

MicroRNAs (miRNA) are short endogenous noncoding RNAs, which are involved in the posttranscriptional regulation of gene expression (Kim et al., 2009) by binding to the mRNA or targeted genes. miRNAs are usually transcribed, like normal coding genes, by RNA polymerase II, and go through a series of maturation steps (**Figure 3**), to make the final approximately 22 nucleotides long miRNA. This then forms the RNA-induced silencing complex (RISC) with Argonaute protein family (Kim et al., 2009), which in turn binds to mRNA by imperfect base pairing. Typically miRNAs anneal to 3′ untranslated regions of mRNAs. Binding of the RISC complex to mRNA inhibits mRNA translation, triggers mRNA deadenylation, degradation, and cleavage (Saraiya et al., 2013).

miRNAs Link the Environment to the Final Functional Protein Levels

miRNAs have been implicated in the translational control of many proteins, including key players in the hypothalamic–pituitary–adrenal (HPA) axis such as the glucocorticoid receptor (GR) (Vreugdenhil et al., 2009), as well as in many pathologies that have been linked to stress such as cardiovascular disease (Devaux et al., 2012), and depression (O'Connor et al., 2012). Stress itself has recently been associated with tissue-specific changes in intracellular miRNA levels in the frontal cortex but not in the hippocampus after restraint stress (Rinaldi et al., 2010), or after anxiety (Haramati et al., 2011). Similarly, after ACTH administration, mimicking HPA axis activation, Riester et al. observed a significant increase in a number of miRNA in the adrenal gland (Riester et al., 2012).

Genetics or Epigenetics?

Genetics versus Epigenetics

Along with the efforts of the International Human Genome Project to complete the first euchromatin sequence of the human genome (Hattori, 2005), a new generation of highly efficient microarray and sequencing-based techniques were developed. With a human reference genome and these powerful techniques new strategies such as genome-wide association studies (GWAS) became possible. In large-scale studies common genetic variants, called single nucleotide polymorphisms (SNPs) were associated with specific traits or phenotypes. The first successful attempt was published in 2005, when age-related macular degeneration was found to be strongly associated with mutations in the gene for complement factor H, encoding a protein involved in the regulation of inflammation (Edwards et al., 2005). However, GWAS showed its limitations when applied to more complex diseases depending both on genetic and environmental factors. The low power and resolution did not allow identifying multiple variants with modest effects and rare variants could only be detected in very large cohorts (Manolio et al., 2009). Moreover, to avoid unreliable or false-positive results, appropriate controls and arduous statistical analyses were essential. GWAS also made the assumption that genetic variants are the main reason for heritable variability in common diseases, which is disputable. For instance, genetic risk scores from a combination of the 24 most discriminating SNPs were statistically linked to coronary artery calcification; however, they explained only 2.5% of the variance observed in this disease (Van Setten et al., 2013). The importance of epigenetic parameters rather than classical genetic factors (such as SNPs or copy number variants) was highlighted in a recent longitudinal study by Baccarelli et al. (2010). The hazard ratio associated with lower global methylation levels and the incidence of cardiovascular disease was significantly higher than, for example, that of preexisting diabetes or smoking (4.0 vs 2.2 or 1.3 for ischemic heart disease; 5.7 vs 3.2 or 2.2 for stroke) and was independent of established risk factors. Although a direct comparison between epigenetic studies and GWAS is difficult, the rs1994016 locus has been shown to be associated with angiographic coronary artery disease with an odds ratio of 1.19 (1.13–1.24 95% CI). This is below the odds ratio of established risk factors such as smoking, and significantly below that of lower global DNA methylation levels (Reilly et al., 2011). There is also growing evidence that a large number of well-established cardiovascular disease risk factors operate through epigenetic pathways including smoking (Talikka et al., 2012), diabetes (Drong et al., 2012), hypertension (Xu et al., 2011), as well as the prenatal environment (Eriksson et al., 2011). Although cardiovascular diseases and psychopathologies may not share the same biological pathways and mechanisms, the latter are equally complex and depend both on genetic and environmental factors.

Epigenetic Modifications Can Be Inherited – DNA Methylation and miRNA

During the past decade it has become increasingly clear that nongenetic information can also be passed on to the next generations.

In 2009, Roth et al. used a rat model of infant maltreatment to investigate the epigenetic mechanisms involved in early-life adverse exposure. In rats with abusing and neglecting mothers expression of the *Bdnf* gene was consistently reduced in the prefrontal cortex where the promoter was also hypermethylated (Roth et al., 2009). Interestingly, the female offspring exposed to early-life maltreatment presented a similar poor maternal behavior and the same altered *Bdnf* DNA methylation pattern. When the offspring of abusive mothers were cross-fostered by normal mothers, methylation levels of the *Bdnf* promoter did not significantly change. This was the first evidence that DNA methylation induced by early-life maltreatment can be transmitted across generations. The exact mechanisms of epigenetic inheritance still remain unclear. In 2013, Rodgers et al. showed that paternal stress reprograms the HPA axis of the next generation regulation through alterations in sperm miRNA composition. Before breeding, male mice were exposed to 6 weeks of chronic stress, either during puberty or adulthood. This stress regimen perturbed the HPA axis of the males and this new phenotype was transmitted to the next generation along with the perturbed gene expression and DNA methylation levels (Rodgers et al., 2013). To elucidate transmission mechanisms, miRNA composition of the sperm of the fathers was investigated. Nine miRNAs were found significantly overexpressed, four of which targeted the de novo methylation enzyme Dnmt3a, and two proteins involved in the miRNA processing, Tnrc6b and Mtdh. These results are suggestive of a dynamic epigenetic transmission across generations. However, the authors could not demonstrate whether the paternal stress or the sperm miRNA composition was directly responsible for the epigenetic reprogramming of the offspring. Nevertheless, these different reports provide strong evidence for epigenetic mechanisms in the inheritance of phenotypes shaped by environmental exposure.

In humans there are so far only few examples of epigenetic inheritance. Fetal malnutrition has effects that persist into subsequent generations. Mothers who were born during the Dutch winter famine (1944–45) and who were exposed to severe malnutrition, had sequelae that were still visible in their own children (Painter et al., 2008). Mothers born with significantly reduced birth weight usually had children with normal birth weight, but of decreased length at birth, and increased ponderal index. Their children also had a 1.8 (95% CI 1.1–2.7) times greater risk of poor overall health in later life.

There is also circumstantial evidence for trans-generational programming of the HPA axis. Children of female Holocaust survivors that developed post-traumatic stress disorder (PTSD) had lower mean cortisol levels across a complete 24-h cycle, than those of survivors without PTSD, suggesting either an inherited programming, or a response to altered maternal behavior during a susceptible period in early life (Yehuda et al., 2007).

Epigenetics in Behavior and Psychology

Epigenetics of the Stress Response

External challenges trigger reactions both in the central nervous system and in peripheral organs. As one of the first reactions, stress activates the neuronal circuits of the HPA axis. Expression

patterns of genes in the limbic brain regions (e.g., prefrontal cortex, hippocampus, amygdala, nucleus accumbens) are modulated and behavioral phenotypes are adopted. In both developing tissues during early life and in fully differentiated adult cells, the transcriptional response to environmental signals is controlled at the epigenetic level (Meaney, 2007; Szyf, 2009). During and acute challenge the effects are transient and, in general, return to basal level once the stimuli disappeared to reinstate the initial homeostasis (McEwen, 2008; Rozanov, 2012), however both the reaction and initial homeostasis can be epigenetically programmed.

Epigenetic mechanisms have been implicated in social and maternal behavior (Weaver et al., 2004), learning and memory (Blaze and Roth, 2013), drug addiction (Vialou et al., 2013), and in several stress-related neurodevelopmental and psychopathological disorders (Kubota et al., 2012; McEwen et al., 2012). Stress response genes have been clearly shown to be susceptible to epigenetic methylation as highlighted in **Figure 4**. For instance GR expression in the hippocampus, essential in regulating the stress response, is susceptible to DNA methylation in both rodents and man (McGowan et al., 2009; Weaver et al., 2004; Turner et al., 2008). Methylation of both the rat and human GR inversely correlates with receptor expression levels (Cao-Lei et al., 2013; Witzmann et al., 2012), however there is some debate as to whether this regulation is due to methylation of individual CpGs (McGowan et al., 2009; Weaver et al., 2004), or wider promoter-wide regions (Cao-Lei et al., 2013; Witzmann et al., 2012).

Figure 4 Schematic representation of the epigenetic regulation of the stress response and the glucocorticoid receptor. After exposure to a programming event such as stress or maternal separation, for example, (Weaver et al., 2004), the glucocorticoid receptor (*Nr3C1*) gene is programmed in the hippocampus, particularly at the histone H3 (Weaver et al., 2004; Weaver et al., 2007), the 1_7 promoter (Weaver et al., 2004), and by miRNAs-18 and 124a (Vreugdenhil et al., 2009). The functional effect of this programming is the phenotypic response to subsequent stress.

In depression, a mental disorder that has been linked to both stress and stress susceptibility, the activity of chromatin modifying enzymes was studied. The genome-wide levels of histone PTMs such as H3Ac, H4Ac, H3K4me3, H3K9me3, and H3K27me3 levels were clearly associated with stress responsiveness in diverse regions throughout the brain (Vialou et al., 2013). Conversely, systemic administration of HDAC inhibitors showed significant antidepressant-like effects in rodent models, but had no effect on unstressed mice (Gundersen and Blendy, 2009; Tsankova et al., 2007).

Current studies suggest highly complex mechanisms that are not limited to the already highly variable chromatin states. There is also evidence that the HPA axis responsiveness and hippocampal GR levels are modulated by miRNAs (Uchida et al., 2008; Vreugdenhil et al., 2009), underlying the stress hypersensitivity of Fischer 344 rats compared with the related hyposensitive Lewis strain (Lytle et al., 2007).

Dysregulation of the HPA axis and the stress response is also often observed in mental disorder. A role has also been proposed for DNA methylation in major depressive disorder (MDD; e.g., GR) (Alt et al., 2010; McGowan et al., 2009) and other mental disorders (Szyf, 2011). Several antidepressants alter global and gene-specific methylation levels in the rodent brain, as part of their therapeutic mechanisms (Milutinovic et al., 2007). Methylation of the serotonin transporter (5-HTT) promoter exacerbates behavioral stress reactivity in monkeys, and increases the risk of mood disorders (Kinnally et al., 2011).

Epigenetics and Behavior

Over the past 20 years there have been many reports of programming of biological systems and behavioral responses. Most of these were associated with defined susceptibility windows. Both in human and animal models maternal stress during gestation increases both anxiety- and depression-like behavior which persists during adulthood. Recent data suggest that epigenetic regulation of gene expression is involved (Sun et al., 2013).

A model in which the epigenetic regulation of behavior has been clearly shown is the Prairie vole (Microtus ochrogaster). These are the only socially monogamous rodents that form male–female bonds. Partner preferences are formed following male–female cohabitation and mating. Recently, Wang et al. facilitated this behavior in females, in absence of mating by inhibiting HDACs. This treatment increased histone acetylation in promoters of the oxytocin receptor (OTR and oxtr) and vasopressin V1a receptor (V1aR, avpr1a) in the nucleus accumbens of the brain producing epigenetic regulation patterns similar to those established by natural mating-induced partner preference. This was interpreted as direct evidence for epigenetic regulation of pair bonding.

Human data are somewhat limited. However, individuals with suicidal ideation or suicide completers have aberrantly downregulated *Bdnf* gene expression and protein levels. Here

Bdnf transcription was shown to be regulated by DNA methylation. The *Bdnf* promoter was significantly more methylated in these patients, linking epigenetic alterations in the brain with suicidal behavior (Keller et al., 2010; Kang et al., 2013).

Epigenetic and Exercise – DNA Methylation

Exercising is widely recognized today to prevent chronic diseases, to decrease the risk of mortality and to increase longevity. The underlying mechanisms are poorly understood but recent epigenetic studies may provide some clues. In 2013, Rönn et al. demonstrated that a 6-month exercise regimen changed the DNA methylation profiles in adipose tissues in healthy men with otherwise low levels of physical activity. Indeed, increases in DNA methylation levels at individual CpGs ranged from 0.2 to 10.9%, affecting adipocyte metabolism and fat storage (Rönn et al., 2013). Increased DNA methylation was shown in particular in genes implicated in obesity and type 2 diabetes. This suggests that common epigenetically controlled loci are involved in different metabolic diseases.

Exercising also showed promise in preventing drug addiction relapses in rodents. For example cocaine seeking was reduced by wheel running in abstinent addicted rats (Peterson et al., 2014). Although this was not tested the authors suspected an epigenetic mechanism, regulating *Bdnf* gene in the PFC region of the brain. A similar study by Sanchez et al. found that exercise may also reduce the relapse vulnerability for nicotine addiction in adolescent rats (Sanchez et al., 2013).

Are There Particular Sensitivity Windows?

Epigenetics plays an important role as an interface between genes and the environment. A wide range of environmental stressors modify the epigenome with dramatic long-term effects on the exposed individual and sometimes even on following generations. Type and time of exposure determine the outcome.

In utero

Epidemiological observations and animal studies demonstrated the importance of epigenetic changes during the developmental period. Environmental conditions, including maternal diet, uterine blood flow, and exposure to chemicals, can have severe consequences on offspring gene expression. Metals in the environment can inhibit specific methylation or demethylation enzymes either by direct binding or indirectly through reactive oxygen species actions. For instance Cadmium crosses the placental barrier and leaves distinct DNA methylation patterns in the newborn DNA. Analysis of DNA methylation associated with Cadmium exposure showed that methylation patterns in newborn white blood cells were disrupted in transcriptional regulation and apoptosis-related genes. The CpGs that were methylated were, importantly, within previously identified transcription factor-binding sites. Kundakovic et al. demonstrated that in utero exposure to environmentally relevant doses of Bisphenol A, a product extensively used in the production of plastics, induces lasting epigenetic disruptions in juvenile mice. The methylation levels of estrogen receptors and Dnmt (1 and 3A) were significantly altered in the cortex of males and the hypothalamus of females. Those epigenetic changes were associated with gender-specific social and anxiety-like behavior, especially sexually dimorphic phenotypes. Also the diet plays an important role in the epigenetics of mother–baby pairs. Epigenetically active enzymes depend on levels of cofactors and metabolites present in the intra- and extra-cellular environment. Some nutrients such as folate, choline, methionine, and vitamin B (folic acid metabolism) are essentials for the establishment and maintenance of DNA methylations both during development and throughout life. Deficiencies resulting from changes in the diet can have severe consequences on gene regulation. In rodents, in utero folate deficiency resulted in embryonic and postnatal growth retardation with long-term brain defects. Kerek et al. showed that early methyl donor deficiency (MDD) in rats may induce persistent brain defects by reducing signal transducer and activator of transcription 3 (Stat3) signaling (Kerek et al., 2013). MDD was also associated with an increased expression of miR-124, affecting Stat3 mRNA expression and activation levels. The authors concluded that impaired Stat3 levels in the brain, caused by miR-124 upregulation, reduce cell proliferation and increase apoptosis that may account for a definitive atrophy of specific brain regions.

The in-utero period is important for the phenotypical programming of the adult. As outlined above, there is growing evidence that even small or transient environmental changes such as maternal infections or stress during pregnancy are major risk factors for later neuropsychiatric disorders such as depression and anxiety (Enayati et al., 2012), schizophrenia (Brown and Derkits, 2010), and autism (Kinney et al., 2008). In-utero stress has recently been found to activate epigenetic mechanisms that could be linked to schizophrenia (Matrisciano et al., 2013). It was proposed that decreased GABAergic gene expression (e.g., glutamic acid decarboxylase 67 and reelin) concomitant with the overexpression of *DNMT* in GABAergic neurons can contribute to the neuropathology of psychotic disorders (Guidotti et al., 2011), and both were induced by prenatal restraint stress (Matrisciano et al., 2013).

Early Life

The principal rodent model of early life care is licking–grooming and arched-back nursing (LG-ABN). Low levels of LG-ABN were demonstrated to directly translate into increased DNA methylation of one particular CpG within the GR promoter, with profound and long lasting effects on the recipients stress response (Weaver, 2007). Enhanced methylation led to reduced GR expression, and cross-fostering of pups from high to low caring mothers demonstrated that the effect was due to the maternal behavior (Weaver et al., 2004, 2007). Maternal separation however did not produce similar differences in DNA methylation of the GR promoter (Daniels et al., 2009).

Translating such rodent data to humans is difficult. Nevertheless, early life adversity may provide some insight into the role of early life in epigenetic programming. For instance the care provided by orphanages has received significant attention, and even in the best institutions the care

cannot match the normal human parent–infant relation. Even in the best institutions employed caregivers working in shifts in charge of 20 children or more (Gunnar et al., 2009) with clear consequences for care quantity and quality (Smyke et al., 2007). A continually changing caregiver is the strongest stressor currently known for human (and nonhuman primate) infants (Johnson et al., 2002). It has also been shown that the changing care provider, in what would otherwise be considered a rich environment, significantly alters both social and emotional behavior for many years (Hodges and Tizard, 1989).

The psychological development of such individuals has been intensely followed in the early years postinstitutionalization including social–emotional behavior, attachment, and relationships (Smyke et al., 2002), peer interactions, and emotion regulation (Hodges and Tizard, 1989) as reviewed by Gunnar et al. (2000). More recently, there have been a large number of correlational neuroimaging studies performed on postinstitutionalized children, including for example PET, diffusion tensor imaging, and electroencephalogram. All of these studies suggest that exposure to institutions in early life induces neuronal mechanisms that underpin behavioral differences later in life. These have recently been extended by physiological studies such as the Minnesota International Adoption Project on postinstitutionalized children that have identified risk factors for cardiovascular diseases (Gunnar et al., 2009), disturbances in the HPA axis which increased with the duration of institutionalization, and epigenetic methylation.

Using a representative series of 27 000 of the 30 million CpGs covering 14 000 genes throughout the human genome, institutionalized children did not have a methylation pattern that was clearly distinct from the parent-raised control children. However, there was a series of 838 genes that showed small, but statistically significant, intergroup differences in methylation levels, that were predominantly (89%) increased after institutionalization (Naumova et al., 2011).

McGowan et al. identified a number of CpG dinucleotides in the GR promoter that were differentially methylated in suicide completers that had been subject to such abuse compared with either control nonabused nonsuicide victims, or to nonabused suicide completers (McGowan et al., 2009).

Adolescence

Development, particularly of certain brain regions, continues until early adulthood, meaning that epigenetic modifications, or programming are not restricted to the perinatal period and childhood (Fraga et al., 2005). For example, the HPA axis plasticity, together with persisting neuroendocrine changes, is maintained during adolescence and into adulthood with consequent phenotypic changes in the stress response (Schmidt et al., 2010). This plasticity is thought to be due to increased DNA methylation, associated with significantly reduced MR and GR levels in certain hippocampus regions (Schmidt et al., 2010), directly affecting the long-term stress response.

There is currently no human data available confirming the underlying epigenetic mechanisms, however studies addressing this such as TRAILS are underway (Bosch et al., 2012). Rodent data show that methylation of the *Gr* in HPA axis tissues, such as the pituitary and adrenal glands, is significantly increased by chronic stress during adolescence (Witzmann et al., 2012). Similarly Gr methylation in the maternal side of the placenta was sensitive to the external environment (Bromer et al., 2013). As such, it would be reasonable to assume that epigenetic mechanisms such as altered DNA methylation underlie the observations of the adolescent environment inducing long-term phenotypic alterations.

Conclusions

Epigenetics promises to improve our understanding of the mechanisms underlying our continued adaption to our environment throughout life. Results, both from animal models and humans, start to reveal specific epigenetic markers and modifications that result in stable phenotype-specific gene expression patterns and behavioral phenotypes. Mechanisms have been implicated in our response to stress or other environmentally challenges at every epigenetic level (chromatin, DNA methylation, and microRNAs).

The three principal epigenetic mechanisms are regulated throughout life with higher epigenetic susceptibility during early life or adolescence. So far tissue-specific epigenetic regulation has been studied almost exclusively on single, permanently regulated genes such as GR or BDNF. First genome-wide studies, however, strongly suggest that transcriptional and translational regulation of many other genes is sensitive to epigenetic regulation. Systematic genome-wide epigenetic studies using cutting-edge next generation sequencing will greatly accelerate our understanding of phenotypic adaptation to our environment.

This will also allow to further exploring epigenetic mechanisms as targets for drug treatment, beyond HDAC inhibitors as antidepressants. However, since HDACs and most other chromatin-modifying enzymes are ubiquitously expressed specific interventions will represent a considerable challenge.

Epigenetics of Brain Plasticity and Behavior

Abstract

Epigenetics refers to changes in gene expression/organism phenotype that occur without altering the DNA sequence. A delicate balance exists between the epigenome (the representative genome that includes all inhibitory and activating, covalent and chemical markers), and the environment that shapes development and long-term plasticity of the human brain, and thus behavioral output. Although epigenetic processes are essential for development and cellular differentiation, they also provide a conduit by which environmental influences can permanently alter neuronal structure and function. From an evolutionary perspective, this provides the organism with a mechanism for instant adaptation. Research is beginning to uncover the means by which epigenetic processes mediate brain development and plasticity and may provide us with the resources needed to restore dysfunctional learning and enhance neuroplasticity in the adult brain.

Introduction

Although cells of a multicellular organism are genetically homogeneous, they differ structurally and functionally from each other based upon the differential expression of genes. Many changes in gene expression arise during development but are steadily maintained throughout life. They are often heritable, transmitted from one generation to the next. Epigenetics refers to changes in gene expression or cellular phenotype that occur without changes to the DNA sequence. Epigenetic processes are essential for development and differentiation; they also transpire in mature cells in response to environmental influences. These epigenetic modifications provide organisms with a means of instant adaptation, whereby gene activity states can be altered by environmental factors and then propagated from one generation of cells to the next.

Brain development and plasticity are highly integrated processes that rely heavily on similar mechanisms of epigenetic programming. Although, often thought of as distinct events both processes use epigenetic factors to alter functioning of the brain. For example, synaptic pruning, a primary mechanism used by the brain during development, is also a key modulator of neuroplasticity. Although there are critical windows for brain development in which epigenetic programs are working at a heightened level, neuroplasticity is an ongoing process that requires steady modification to signaling cascades, gene expression, and protein production. The main purpose of this article is to describe the influences of epigenetics on brain development and plasticity. While this article will attempt to distinguish between the two processes, there is considerable overlap, and it may be difficult to differentiate where one mechanism begins and the other ends.

Neurodevelopment refers to the processes that generate, shape, and reshape the central nervous system (specifically the brain) from embryogenesis to the final years of life. Although brain development typically follows a predictable pattern that is generated by a genetic blueprint, experiences during this sensitive period have the ability to alter epigenetic patterns of many genes. Characterization of methylation patterns in the normal brain indicates that epigenetic alterations are dynamically regulated and region dependent. Temporal analysis demonstrates significant epigenetic activity in the prenatal period, followed by a marked slow decline after birth that continues with aging. This temporal arrangement is consistent with genome-wide demethylation at the point of conception followed by rapid re-methylation of the genome that is maintained throughout life. Several studies show that methylation of the brain's epigenome increases with age, with regional differences that coincide with maturational rates of the brain (see Ladd-Acosta et al., 2007; Siegmund et al., 2007). Importantly, these studies not only demonstrate the increased opportunity for epigenetic modification in the early years, but also emphasize the continuous nature of epigenetic programming and neuroplasticity.

Epigenetics permeates all aspects of development, especially in the brain. The mammalian brain is unique in this respect as it develops intimately with the environment, both prenatally and postnatally in the context of all experiences. These experience-induced changes produce stable gene-expression modifications that alter gene transcription throughout life and stimulate specific behavioral and psychological outcomes. The adaptive nature of the brain is produced by the dynamic relationship that exists between the epigenome, environment, and behavioral outcomes.

Similarly, a fundamental property of the brain is its propensity to change. Neuroplasticity refers to changes in neural pathways and synapses, which occur in response to changes in behavior, environment, and other neural processes. Neuroplasticity occurs at a variety of levels that range from behavioral (e.g., learning) to structural (e.g., cortical reorganization following injury). Common belief has changed from the previous position that the brain is a physiologically static organ, to the consensus that the brain is plastic only during critical windows, and finally to the current conviction that the brain remains plastic throughout life, but that the permeability to change waxes and wanes with maturational state and plasticity reserves. Although changes in the brain/neuroplasticity can be transient (i.e., fluctuations in neurotransmitters) or persistent (i.e., alterations to dendritic morphology or synaptic pruning), each modification requires epigenetic activity. For example, dendritic arborization can only occur following alterations in protein production that result from changes in

 http://dx.doi.org/10.1016/B978-0-08-097086-8.55058-2

gene expression. Similarly, the neurogenesis associated with improved hippocampal functioning is dependent upon upregulation of specific growth factors, an epigenetic modification.

Mechanisms of Epigenetic Programming

The DNA sequence is only a foundation for understanding how the genetic program is read. A second layer of interpretation is required to fully appreciate the possibilities arising from the original sequence. There are 3 main mechanisms of epigenetic regulation used to transmit these genetic adaptations: RNA regulation, posttranslational modification to histone proteins, and the most commonly studied DNA methylation (see Figure 1).

RNA Regulation

Evidence indicates that RNAs direct many aspects of chromatin regulation. A sophisticated RNA regulatory network involves RNA editing and non-protein-coding RNAs that orchestrate an aspect of epigenetic programming. Non-coding RNAs (ncRNAs) dominate the transcriptional output of mammals and regulate many levels of gene expression during development. RNA-binding co-regulators are recruited to transcriptional units by gene-specific ncRNAs to modulate chromatin structure. ncRNAs may recruit transcriptional repressors or transcriptional activators functioning in both gene activation and gene silencing. microRNAs are posttranscriptional regulators that bind to the complementary sequence of mRNA in the 3′ untranslated region (UTR) usually resulting in gene silencing. RNA regulation is a continuous process involved in long-term memory formation, context-specific behavioral responses, and cellular development and differentiation (Mehler and Mattick, 2007).

Posttranslational Modification to Histone Proteins

Epigenetic programming via posttranslational modification of histone proteins occurs by altering the accessibility of the transcriptional machinery to the DNA. Posttranslational modification to histone proteins includes processes such as

Figure 1 The cartoon demonstrates the three main levels of control utilized by the cell to regulate expression of specific genes and maintain epigenetic patterning. (a) Gene expression is regulated by microRNAs that bind to transcribed sequences of mRNA prior to protein translation. (b) DNA methylation is the most stable form of gene silencing, whereby methyl groups (M) are bound to cytosine residues in a gene's promoter region. (c) Histone modifications, including methylation (M), acetylation (A), ubiquination (U), and phosphorylation (P), are commonly used mechanisms that alter accessibility of transcriptional machinery to DNA sequences.

methylation, acetylation, and ubiquitination. Histone acetylation is the most commonly studied posttranslational modification. Acetylation is associated with decondensation of chromatin and increased transcriptional activity whereas histone deacetylation is linked to transcriptional repression (Fagiolini et al., 2009). The acetylation state is controlled by histone deacetylases (HDACs) and histone acetyltransferases (HATs) (Fagiolini et al., 2009). Histone methylation is generally associated with inactivation of transcription and condensation of the chromatin to a highly compact form.

DNA Methylation

DNA methylation is the primary contributor to the stable maintenance of particular gene expression states (Jaenisch and Bird, 2003). Gene silencing via DNA methylation occurs when a methyl group binds to the cytosine residue of a CpG island (Champagne, 2010). This addition attracts other methyl-binding proteins to the site; when these proteins are bound to the gene's promoter region, RNA polymerase cannot bind and the gene cannot be transcribed (Champagne, 2010). This process does not alter the DNA sequence. It merely limits access to the gene's promoter region. Switching between expression and silence is unlikely to occur by chance due to the presence of self-reinforcing mechanisms (Jaenisch and Bird, 2003). DNA methylation is tightly regulated; epigenomes are highly organized and surprisingly nonrandom with respect to methylation patterns (Borrelli et al., 2008). There are few methylation differences from neuron to neuron, or even neuron to neuron in two unrelated individuals.

Genomic Imprinting

With the exception of genomic imprinting, each parent contributes a single copy of all autosomal genes to their offspring at the moment of conception. Genomic imprinting is an epigenetic phenomenon independent of typical Mendelian inheritance, whereby specific experience-dependent changes can be propagated from one generation to the next. In genomic imprinting, parental genes are methylated in a parent-of-origin-specific manner. This heritable methylation pattern completely silences one parental allele, ensuring all of the genetic information is derived from the other parent. Therefore, genomic imprinting leads to selective expression of one of the two alleles, and has the potential to significantly influence brain function and behavior by altering paternal contributions to neurodevelopment and also long-term epigenetic programming (Wilkison et al., 2007).

Prenatal Epigenetic Influences on Brain Development and Plasticity

An organism's ability to survive is dependent upon its capacity to adapt to its environment. For mammals, this adaptive response begins prenatally, as the fetus adjusts to the intrauterine environment, with the assumption that the prenatal and postnatal environments are similar. The prenatal brain is exceedingly susceptible to environmental influence, as this is a sensitive period for brain development (Fagiolini et al., 2009). Gluckman and Hanson (2005) hypothesized that the epigenetic modifications experienced by the fetus in response to the intrauterine environment prepares the fetus for the particular environment it is likely to be exposed to later in life. These early-life responses, also known as fetal programming, occur rapidly in a single generation, to increase the offspring chances of survival. In response to environmental stimuli, the brain changes at the genetic, cellular, and structural levels. Throughout an organism's lifespan there is a continuous reciprocal relationship between environmental stimuli and epigenetic response. Protein synthesis is in a constant flux, resulting in a brain that demonstrates remarkable plasticity. However, evidence now indicates that if brain changes are made to compensate for prenatal disturbances, plasticity reserves may not be available later in life.

The prenatal period is a critical time for epigenetic processes, many of which are vital for development and differentiation, but others have been shown to influence growth, metabolism, and behavior. There is increasing evidence to show that maternal nutrition, physiology, and psychological states epigenetically influence the developing fetus (Champagne, 2010). Epidemiological studies of cohorts prenatally exposed to famine are associated with increased risk for schizophrenia, affective disorders, and other neurodevelopmental disorders. Many studies have linked schizophrenia to early-life adversity and differential epigenetic patterning, with postmortem analysis of brain tissue from schizophrenic individuals demonstrating aberrant epigenetic marking and altered CpG methylation of over 100 genes. Similarly, prenatal maternal stress has been associated with a plethora of negative long-term neurological outcomes. Studies demonstrate that gestational stress effects expression of hundreds of genes in the developing brain, including DNA Methyl Transferases (DNMTs), HDACs, and HATs. The implications of these findings are significant, as the epigenetic changes identified in hundreds of genes persist long after the initial insult, altering the plastic response to all future experiences.

Postnatal Epigenetic Influences on Brain Development and Plasticity

Epigenetics and Postnatal Brain Development

Although epigenetic mechanisms have been intrinsically implicated in mediating the heightened levels of neuroplasticity early in development, the ongoing plasticity demonstrated by the developing and mature brain also results from epigenetic processes. Synaptic networks and cortical tracts are extremely permeable to sensory stimulation and environmental influence during 'critical periods' of postnatal development. The heightened level of epigenetic activity that permits substantial learning and reorganization during these temporal windows has been attributed to the activation and subsequent inhibition of specific molecular pathways and signaling cascades (Fagiolini et al., 2009). Research demonstrates that HDAC, HAT, and DNMT activity is essential for neuroplasticity during these time periods and knocking out any of these genes disrupts cortical organization and function. In addition, the maturation of myelin (which often accompanies closure of critical windows) is associated with epigenetic activation of Nogo receptors, a network known to block neuroplasticity. It

appears that critical windows are associated with heightened epigenetic activity, but once windows close stable inhibitory epigenetic marks are added to the genome. Although these inhibitory marks are less responsive to environmental influences, the normal decrease in plasticity associated with the hyper-methylated aging brain can be reinstated with HDAC and DNMT inhibitors. HDAC and DNMT inhibitors have been administered via nutritional supplements and drug combinations, but further work is necessary to understand the mechanisms underlying the specificity and persistence of these alterations.

Epigenetics and Brain Plasticity

In addition to epigenetic regulation of postnatal brain development, epigenetics is also involved in learning and memory, and experience-dependent neural plasticity. Studies demonstrate that the adult neuronal response to environmental stimuli via epigenetic mechanisms and epigenetic regulation of a multitude of genes is necessary for plastic changes in the adult brain. Memory consolidation and long-term potentiation (LTP) are dynamically regulated by cascades of signaling events that are dependent upon changes in gene expression. In the hippocampus specifically, the formation of a memory following a contextual fear-learning paradigm is associated with histone acetylation, DNA methylation, and transcriptional activation of memory-enhancing genes such as Reelin and BDNF. Inhibition of DNMTs can actually block memory formation following contextual fear conditioning, whereas inhibition of HDACs enhanced formation of these memories. Furthermore, the activity of epigenetic programmers involved in learning and memory is time-specific and regionally dependent. Researchers have shown that the time period immediately following an electric shock is associated with altered methylation patterns in the hippocampus but that gene expression profiles in the neocortex preserve the memory days later (see Miller et al., 2008; Miller and Sweatt, 2007).

As it is now known that epigenetic programming is involved in normal learning and memory, reprogramming epigenetic modifiers can also restore dysfunctional learning processes. Despite prevailing evidence demonstrating the powerful effects of environmental enrichment (EE) on neuroplasticity, the underlying mechanisms have only recently been examined. EE has proven efficacious in reducing neurodegeneration and increasing neuroplasticity and long-term cognitive reserves. Recent evidence suggests that in the adult brain, EE modulates NMDA signaling pathways in the hippocampus, increases histone acetylation, and decreases global methylation patterns; each of which are epigenetic modifications associated with increased plasticity. Interestingly, EE can restore dysfunctional learning in cognitively impaired mice by increasing histone acetylation in the hippocampus and neocortex. Furthermore, this epigenetic modification is heritable and transmitted across generations; offspring of cognitively impaired mice exposed to EE show no deficit-forming memories related to contextual learning, even when cross-fostered to nonenriched mothers (Arai et al., 2009).

Abstract

Epilepsy is a common neurological disease that is characterized by an increased likelihood of experiencing seizures: events of pathological, hypersynchronous activity of neural networks. The development of epilepsy is influenced by complex interactions between genes and the environment, and is most common in young and old populations. About 60–70% of patients can control seizures with antiseizure drugs, which inhibit seizure development and propagation. The remaining individuals often require surgical resection or novel methods of controlling seizures. Current challenges include identifying therapeutic targets that prevent the development of epilepsy, understanding unexpected deaths, and addressing the causes of behavioral impairments and brain damage.

Epilepsy is one of the most common neurological diseases and is marked by the occurrence of periods of excessive neural synchrony (an electrographic seizure) that occur following innocuous stimuli that would not cause a seizure in a non-epileptic brain. Thus, the core concept of epilepsy is that the brain has a chronically low seizure threshold and is subjected to recurrent seizures. Epilepsy is a significant cause of morbidity and can be fatal in some instances. While our understanding of this disease has grown tremendously over the last century, much of its causes and consequences are still poorly understood. The purpose of this article is to provide a brief summary of current knowledge, identify knowledge gaps, and give insight into recent developments and potential treatments for epilepsy in the future.

Defining Seizures and Epilepsy

Given the heterogeneity of seizure types, there is often confusion when defining seizures and epilepsy. Recognizing this, the International League Against Epilepsy (ILAE) publishes reports that define and classify seizures and epilepsy. Currently, the ILAE defines an epileptic seizure as "a transient occurrence of signs and/or symptoms due to abnormal excessive and synchronous neuronal activity in the brain" (Fisher et al., 2005). Epilepsy is defined as "a chronic condition of the brain characterized by an enduring propensity to generate epileptic seizures, and by the neurobiological, cognitive, psychological, and social consequences of this condition. The definition of epilepsy requires the occurrence of at least one epileptic seizure" (Fisher et al., 2005). Definitions of epilepsy have been subject to change over the years, and may be modified again in the future, as knowledge in the field of epilepsy is constantly being updated.

Focal versus Generalized Seizures

Seizures are classified by how neural networks that participate in seizures are distributed. Focal seizures (previously referred to as partial) arise from a synchronous, hyperactive local region of the brain. The symptoms of a focal seizure depend on which neural networks participate in the seizure. Thus, focal seizures may have motor, sensory, autonomic, and/or psychic features. Focal seizures are further classified as to whether awareness is retained or altered (dyscognitive).

Generalized seizures may start as a focal seizure (as in focal epilepsy), but spread rapidly and bilaterally to distributed networks in both hemispheres. Alternatively, in primary generalized epilepsy, seizures begin in more widespread neural networks. Generalized seizures can further be classified as follows:

- tonic – clonic (formerly grand mal) – rigidity followed by rhythmic muscle contractions;
- absence (formerly petit mal) – brief periods of staring, blinking, or movements;
- clonic – rhythmic muscle contractions;
- tonic – Contraction of flexor and extensor muscles, rigid posture;
- atonic – Loss of muscle tone resulting in drop attacks; and
- myoclonic – Jerking of extremities symmetrically.

Etiology

While a typical mammalian brain can have a seizure induced through a variety of means including; electrical stimulation, lesions, convulsant drugs, and rapid withdrawal from chronic alcohol exposure, the causes of epilepsy are classified as genetic, structural-metabolic, or unknown. Genetic epilepsies (formerly termed idiopathic) occur as a result of mutations that directly promote both seizures and epilepsy. For example, mutations in genes that encode ion channels can contribute to abnormal excitability and stimulate a state of hypersynchrony. As the name suggests, structural/metabolic epilepsies result from brain abnormalities in structure and/or metabolism. For instance, epilepsies that develop from injuries to the brain (e.g., stroke, trauma) are classified as structural/metabolic. In the case, where there are no known structural/metabolic and genetic abnormalities, they are termed unknown. The number of unknown epilepsies continues to shrink with the

development of superior technologies that identify structural, metabolic, or genetic causes.

It should be noted that the boundaries between these epilepsies are not clear-cut. Genetics and changes in brain structure and metabolism likely interact to produce epilepsy. Genetic predispositions, for example, may make an individual more likely to develop epilepsy after a brain injury. Thus, the etiology of epilepsy should be understood as an interaction of genes and the environment.

Status Epilepticus

For the most part, seizures are self-terminating. In some cases, however, the driving force of the seizure does not abate, often due to a brain insult or drug withdrawal, and pharmacological intervention with a fast-acting benzodiazepine, barbiturate, general anesthesia, and/or ketamine is required to end the seizure. Status epilepticus is the term given to this life-threatening condition where seizures do not self-terminate. Mortality due to status epilepticus is much more common in adults than children (26 vs 3%, respectively) (DeLorenzo et al., 1996) and survivors often live with significant morbidity due to brain damage. Previously, 20 min of continuous seizure activity or bouts of seizure activity without regaining awareness was the accepted duration before pharmacological intervention was recommended. Today, however, 5 min of seizure activity is recommended because we have learned that most seizures terminate in less than a few minutes and seizures over 5 min in duration are unlikely to self-terminate (Lowenstein et al., 1999).

Sudden Unexpected Death in Epilepsy

Sudden unexpected death in epilepsy (SUDEP) refers to sudden death in patients with epilepsy where there is no identifiable cause of death (e.g., status epilepticus, drowning, falling), based on pathology and toxicology (Tomson et al., 2008). Most evidence suggests that SUDEP occurs during or, more often, after a seizure. Therefore, SUDEP is not entirely 'unexplained,' since recent seizures seem indirectly causal, but the direct cause of death remains unknown. Respiratory and cardiac failure may be common causes of death, but events leading up to this have yet to be characterized. Given that people with epilepsy die unexpectedly at a rate that is 24 times that of the general population (Ficker et al., 1998), SUDEP remains a large health challenge.

Epidemiology

Banerjee et al. (2009) has reviewed studies from around the world and concluded that the prevalence of epilepsy ranges from 0.2 to 4.1%. It is also noted that developed nations have lower prevalence and incidence of epilepsy as compared to developing nations. Some studies suggest that low-socioeconomic status, male gender, and some races have a higher prevalence of epilepsy, although these results are not consistent.

Seizures are most common in early development and senescence. In early life, the brain may be subjected to numerous factors that provoke seizures like hypoxia, inflammation, injury, and poor pre- and postnatal care. Febrile seizures are the most common type of seizures in infants and young children with up to 5% of children between 6 months and 5 years having had at least one febrile seizure (Reid et al., 2009). Although early life seizures have often been considered benign events, longer seizures are associated with an increased risk of developing epilepsy later in life. The aged brain is also subjected to events that increase the likelihood of seizures. Stroke is the most common cause of seizures in the elderly but epilepsy can also be caused by neurodegenerating diseases, dementia, tumors, head injury, and infection.

Diagnosis and Treatment

Diagnosing epilepsy no longer requires a physician to witness a seizure. In fact, epilepsy can often be diagnosed with an electroencephalogram (EEG) when a patient is not experiencing seizures. An EEG can detect abnormal changes in electrical potential across electrodes secured to a patient's scalp. In some epilepsies, however, interictal (between seizures) EEG can be completely normal and physicians will need to employ other diagnostic strategies. Patient or witness descriptions of seizure events (e.g., duration, loss of awareness, behavior, auras) will give a physician an idea of what type of epilepsy is most likely. Other techniques, such as Magnetic resonance imaging (MRI), can help diagnose epilepsy by identifying structural abnormalities associated with epilepsy (e.g., scarring). It is also important to conduct blood work to ensure seizures are not a consequence of a separate condition.

The first line of treatment for epilepsy is antiseizure drugs (ASDs), which inhibit seizure development and propagation. ASDs are often referred to as anticonvulsant and antiepileptic drugs, although these terms are inaccurate. ASDs have a diverse range of mechanisms to raise seizure thresholds. Common mechanisms include enhancing the action of the inhibitory neurotransmitter GABA (e.g., gabapentin), stabilizing the inactive state of sodium channels (e.g., carbamazepine, valproate), and inhibiting T-type calcium channels (e.g., ethosuximide). Most ASDs have broad mechanisms of action, many of which are unknown, that overlap with other ASDs. Most people with epilepsy will be able to work with their physician and find a drug and dosage that causes few side effects.

Unfortunately, 30–40% of people with epilepsy are unable to completely control seizures with ASDs and are termed refractory, pharmacoresistant, or intractable. Children and some adults with refractory epilepsy often benefit from the ketogenic diet: a high fat, low carbohydrate diet with anticonvulsant action. In adults, surgical resection of epileptogenic tissue is the most common treatment for intractable epilepsy and has a success rate of 70%. More recently, deep brain stimulation (DBS), a very successful treatment for Parkinson's disease, may be useful in refractory epilepsy patients. Bilateral stimulation of the anterior thalamus has been successful at reducing seizure frequency in many patients and DBS shows promise but more research is needed.

As is evident from the examples above, epilepsy treatments are focused on neural excitability. Even though new ASDs have

been developed, the percentage of patients with refractory epilepsy has not changed. In other words, new ASDs are still not treating intractable epilepsy, although they may have fewer side effects. Current research suggests that glia may be an appropriate pharmacological target (Devinsky et al., 2013), especially in intractable epilepsy. Astrocytes play a very important role in regulating the extracellular space, which can have a profound influence on seizure susceptibility. Astrocytic membrane proteins Aquaporin-4 and Kir4.1 regulate water and K^+ buffering, respectively, and are impaired following seizures. As a result of inadequate buffering, neural excitability is increased and may contribute to epileptogenesis. Given the importance of glia in regulating synaptic transmission, inflammation, blood flow, and neural excitability, more research is needed to identify potential therapeutic targets.

Consequences of Seizures

There are numerous structural and functional changes that occur after seizures, which give rise to specific behavioral impairments. To understand how the brain changes following seizures, it is important to understand what happens before, during, after, and between seizures.

Preictal Period

The preictal period occurs just before a seizure and is increasingly becoming a focus of epilepsy research. Identifying reliable markers that are expressed during the transition from preictal to ictal may allow patients to predict seizure onset and allow intervention. EEG changes in network activity can be observed minutes to hours before a seizure. There are also pronounced blood flow changes before seizures that may aid in identifying seizure onset (Baumgartner et al., 1998). Using functional MRI, Federico et al. (2005) found that a signal (Blood Oxygen Level Dependent) could be detected several minutes before seizure onset. Future treatments may employ implanted devices that measure these changes and intervene with electrical stimulation or pharmacological agents prior to a seizure.

Ictal Period

The intense neuronal firing during the ictal period is thought to be ultimately responsible for neuronal death, especially following prolonged seizures. The exact mechanism that leads to cell death has not been definitively determined but a large influx of calcium, which can lead to programmed cell death likely plays an important role. Following prolonged and severe seizures, as with status epilepticus, brain damage can be quite extensive.

Postictal Period

Following seizures, many genes are upregulated, including proinflammatory cytokines. These cytokines are thought to underlie the increased blood–brain barrier permeability that follows seizures as well as activation of astrocytes and microglia. Stains that select for dying neurons show that neuronal death peaks 12 h after a seizure and is thought to be due to the proapoptotic mechanisms activated during the ictal period.

Behaviorally, seizures often lead to deficits that are specific to brain regions involved in the seizure. In 1849, Dr Robert Bentley Todd first described a phenomenon that bears his name: Todd's paresis. It is frequently defined as motor paralysis contralateral to the seizure but may also affect a variety of sensory, motor, or cognitive processes, depending on where the seizure occurred. Furthermore, patients with medial temporal lobe epilepsy (TLE) and animal models of TLE have pronounced spatial memory deficits after seizures. These deficits last several minutes to hours and cannot be explained by flattening of the EEG. A few case reports have noted that Todd's Paresis is accompanied by reduced blood perfusion (Yarnell, 1975), but this has yet to be fully explored. There are data that show that this postictal period is associated with a pronounced ischemia/hypoxia that in turn appears to be responsible for the behavioral impairment (Teskey and Farrell, 2012).

Interictal Period and Comorbidities

With repeated seizures, changes in the brain occur that result in permanent behavioral disruption even when seizures are not occurring. These behaviors are often difficult to describe in patient populations because of the confounding effects of ASDs. Animal models have shown that seizures cause network reorganization and greater excitability, which disrupts the behavioral output of that brain region. With repeated neocortical seizures in rats, for example, movement representations on the motor cortex have lower thresholds, are much larger and have more multiple movements (Teskey et al., 2002). Behaviorally, these characteristics manifest as poor performance on skilled motor tasks. Thus, behaviors in the interictal period are specific to seizure networks and result in specific comorbidities (see Section Focal versus Generalized Seizures).

In patients with TLE, the most common pathology is hippocampal sclerosis, which is characterized by severe neuronal loss and an overabundance of glial cells, and is found specifically in the CA1 and subiculum of the hippocampus. It is important to note that MRI does not always detect hippocampal sclerosis. Recent developments in animal models suggest that glia may play a large role in epileptogenesis (see Section Epidemiology). Briefly, astrocytes create an extracellular environment that raises the excitability of neurons. Repeated seizures are also associated with production of inflammatory agents. Together, these signaling molecules enhance neuronal excitability. In sum, many glial-mediated changes occur in epileptic tissue and result in hyperexcitable tissue, which may explain interictal behaviors and the increased likelihood of experiencing seizures.

People with epilepsy also have neuropsychiatric disorders at higher rates than the general population. A 2011 survey of 172 959 people revealed that people who reported having epilepsy were significantly more likely to indicate that they had anxiety, depression, bipolar disorder, ADHD, sleep apnea, and movement disorders/tremors (Ottman et al., 2011). Depression is the most common comorbidity with 32.5% of

people with epilepsy also reporting depression. Interestingly, the relationship is bidirectional: depression increases the risk of epilepsy and epilepsy increases the risk on depression. While these comorbidities help our understanding of epilepsy, it is important to consider other factors that may increase the prevalence of comorbidities (e.g., antiepileptic drugs, psychosocial factors).

Conclusion

Our understanding of epilepsy has grown tremendously over the years. Epilepsy is influenced by interactions of genetic and environmental factors, which create brain changes that make seizures more likely. Epilepsy is more common in the young and old, partly due to seizure-promoting factors that are commonly experienced at these ages. New generations of ASDs may have decreased side effects for patients, but the amounts of refractory cases still remain to be 30–40%. Surgical resection of epileptic tissue is still the gold standard for intractable cases, but emerging technologies (e.g., DBS, seizure monitoring implants) could provide more treatment options. Furthermore, the role of glia in the CNS has been intensely studied in the last decade and potential implications in epilepsy are being explored. Given the role of glia in epileptogenesis, glial-targeted therapies could provide a new avenue of treatment – the development of epilepsy (i.e., not just the prevention of seizures). Ongoing challenges in the field of epilepsy are refractory cases, SUDEP, and understanding postictal and interictal phenomenon.

Episodic Memory

Costanza Papagno, Università di Milano Bicocca, Milano, Italy

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Episodic memory is the memory of events in our own past and is a form of long-term, declarative memory. But how are episodic memories formed and how are they retrieved? The mechanisms and structures that determine whether an experience will be remembered or forgotten, the stages of memory processing, namely encoding, consolidation, and retrieval will be described, as well as the role of context in such processes.

Introduction

Information that is acquired in the course of experience, persists, and so can be consciously retrieved long after the experience is past is 'episodic' memory. However, episodic memory is not only memory of events in our personal past, but it also helps us to stay oriented in the present, and make plans for the future. This type of memory involves oneself as a participant and therefore it seems to be synonymous with autobiographical memory. Wheeler et al. (1997) have suggested that the type of awareness evident during retrieval primarily characterizes episodic memory whereas the content of the retrieved material (self-related) defines autobiographical memory. Episodic memory involves reexperiencing and being aware of the continuity of the experiencing self across time; autobiographical memory refers to the information that involves the rememberer but need not to entail the same subjective awareness (Gilboa, 2004). Autobiographical reexperiencing is only one aspect of autobiographical memory and seems unique to humans (more details about the distinction between episodic and autobiographical memory can be found in Conway, 2001).

The Canadian psychologist Endel Tulving in 1972 defined episodic memory as the conscious knowledge of temporally dated, spatially located, and personally experienced events or episodes. Episodic memory can be contrasted with semantic memory, our generic knowledge of the world. The relationship between the two remains controversial: one view suggests that semantic memory is simply the accumulation of many episodic memories for which the detailed contextual cue has disappeared, leaving only generic features (Squire, 1992), while Tulving (2002) postulated that episodic memory evolved out of semantic memory; many animals possess well-developed knowledge of the world and are capable of acquiring new information. Early humans were like these animals, but during evolution, episodic memory emerged. Its operations require, but go beyond, the semantic memory system.

Episodic memory has a context: when you recollect details about some episode, you are engaged in a sort of 'mental time travel,' and you are aware that the information you hold about it is bound to a particular experience. When events are retrieved, they are reexperienced in a quasiperceptual way, with conscious awareness. Every episodic memory involves a mental representation of the self as the agent or recipient of some action, or the experiencer of some state. Moreover, we have a conscious awareness that our reexperience of the past is different from our ordinary awareness of what is going on in our environment: the term 'autonoetic' awareness refers to the special kind of consciousness that allows us to be aware of the subjective time in which events happened. Consequently, episodic memory requires a subjectively sensed time.

Yet, the way episodic memory is tested is through learning lists of words (testing the to-be-learned material by means of free recall, cued recall, or recognition), stories recall or nonverbal material recall (such as immediate and delayed reproduction of spatial sequences or meaningless pictures): in such a way, one of the main features of episodic memory is missing, namely the temporospatial context. As Tulving (2002) pointed out, traditional laboratory experiments are almost invariably concerned with 'what,' but not with 'when' and 'where.' Therefore, episodic memory tests, for instance recalling lists of unrelated words, do not exactly deal with episodic memory. More recently, paradigms assessing also when or where a particular item was learned have been used.

Episodic memory processing involves three stages, interacting with each other: 'encoding,' 'consolidation,' and 'retrieval.' We experience an event and some aspects of this event get encoded. Encoding initiates a series of processes that take time – consolidation – and produces a memory trace. The stored memory trace can be retrieved. The original experience may involve the emotional arousal that was associated with the episode and this emotion may be remembered when the corresponding event is retrieved. Almost invariably, events are interpreted in a meaningful way through semantic knowledge. Such a complex process requires the activity of several brain structures and mechanisms.

Encoding

The term encoding indicates the various processes by which information is transformed into a memory representation. Episodic encoding requires the binding together of the various features of an event into an integrated memory representation. I make an experience, for example, I meet people during a party in a particular place one evening at a certain time of the year; I notice how they are dressed and look like, their voice and accent, the perfume, and perhaps I also think that they are boring or interesting people, therefore interpreting the experience and coloring it with an emotion. All of that produces a mental representation that records some or all of the aspects of this episode. The major feature of episodic representations is, therefore, that they associate together very different kinds of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.51032-0

information, including perceptual and semantic characteristics of objects, and how they are located in space and time relative both to each other and the self.

Several factors can affect encoding. One is the level at which we attend the experience, namely the amount of attention that we devoted to it, and the level at which we elaborate, interpret its meaning, relate it to other experiences and organize it.

In 1972, Craik and Lockhart developed a theory, the so-called 'level of processing' theory, which gave particular emphasis to the depth of processing. They suggested that the amount of information retained in long-term memory depends on how deeply it is processed during learning. For example, a given stimulus, say a word, can be processed in terms of its physical superficial features, or converted into its sound, or by evoking its meaning. Processing the word in terms of its meaning, requiring one to create a more durable memory trace, is deeper. In a later study, Craik and Tulving (1975) asked three groups of healthy participants to make judgments about viewed unrelated words: a group decided whether these words were written in lower or upper case, a second group had to make a rhyme judgment with a different word, and a third group had to decide whether a word fitted in a sentence. Afterward, the three groups were submitted to a recognition task, in which they had to categorize a list of words as either those that had already been presented or as new words. Participants who had to retrieve the appropriate meaning of the words (to decide whether they fitted in the sentence) obtained the best performance. Episodic memory would benefit, therefore, from this deep, semantic processing. However, patients with 'semantic dementia' who cannot meaningfully interpret episodes encode and recognize the perceptual features of experienced objects in a relatively normal way and they also can cope with spatiotemporal contexts (Papagno and Capitani, 2001). This suggests that adequate representations of perceptual features and spatiotemporal context can probably be made even without semantics.

The Craik and Tulving's experiment is an example of incidental learning, since participants were unaware that they would be tested for memory. There was not a purposeful intention to learn. This explains how we retain everyday experiences that we do not deliberately attempt to encode. However, attention can play a crucial role in encoding (see below).

The concept of processing depth is not particularly clear, and has been repeatedly criticized. It would be better explained in terms of richness and flexibility of the system. These two characteristics make semantic coding widely used in long-term memory: information that is encoded in terms of a rich and detailed description is likely to be more accessible than material that is processed in terms of simpler schemes. Generally, an effortful encoding leads to better recall. One is more likely to remember later the solving of a difficult problem than that of an easy one. A deeper elaboration of stimuli may result in distinctive records that are more discriminable from other encoded events and therefore can be more easily retrieved.

As mentioned, learning can be incidental or intentional. One reason for poor encoding is lack of attention. A failure to attend an event has as a consequence a reduced ability to retrieve it in the future, as it can be seen in eyewitness, when we can discover that many details of a scene have been completely ignored. Encoding is also reduced when we attend two tasks simultaneously. When we are performing a task, for example, cooking some elaborate meal without being an expert chef, and someone talks with us, we are more likely to forget what has been told, since we were involved in a distracting performance. Accordingly, the role of attention has been explored in laboratory, using dual task paradigms. In this type of task, the participants' attention is divided between encoding the information presented and performing a secondary task (for example, monitoring the position of an asterisk on a computer screen and press a button when it changes). This has detrimental effects on memory performance relative to conditions where full attention is paid to encoding the items (Craik et al., 1996).

A third aspect that helps encoding, beside level of processing and attention, is 'organization.' When participants are instructed to organize some material, and subsequently they are tested for recall, they retain this material just as well as participants who are instructed to learn it. In other words, there are major advantages in subsequent recall when participants are required to organize material. The term organizing generally refers to the grouping of items on the basis of shared semantic attributes (Gershberg and Shimamura, 1995), due to the familiarity that people already have with the to-be-learned material. Thus, a task requiring organization of material will overlap considerably with a deep encoding task since it requires processing of its meaning. Organizing has the additional requirement of manipulating material on the basis of its similarities or differences to other material.

A fourth variable affecting encoding is the 'distribution of practice in time.' The German psychologist Hermann Ebbinghaus (1850–1909) showed that it is better to distribute learning over two days relatively evenly rather than concentrate all in one day. He tested himself in learning meaningless consonant-vowel-consonant syllables (such as GUW, BEX), using both massive and distributed practice. At recall, he noticed that a suitable distribution of repetitions over time was more efficient than the massing of them in a single session, showing that distributed practice is better for encoding than massive practice. What is not clear, however, is how long the intertrial interval should be. This spacing effect can be related to several reasons: for example, attention can decrease when trials are massed together. When trials are spaced, the context can change enhancing a richer memory trace and additional retrieval routes to our memory. Indeed, the processing performed for the initial encounter and for repeated trials in massed practice is likely to be very similar: items are presented in the same context and in the same way. Distributed practice, on the other hand, fosters greater encoding variability: the context can change. A stimulus is more likely to be remembered when it is processed in different ways across trials. More recent research (Litman and Davachi, 2008) has suggested that the benefit of distributed learning is enhanced memory consolidation. More specifically, the time period of consolidation between distributed encoding session helps to stabilize memory traces. In addition, the reactivation of memory representations during the second encoding session may further facilitate consolidation.

The Context Effect

Context plays a crucial role. The effect of context at encoding depends on the contextual similarity between the target information and any subsequent interfering information.

When contextual information provides enough details to uniquely specify an event and distinguish it from other similar events stored in memory (Murnane et al., 1999), it reduces interference. This is evident in our everyday experience when retrieval of information does not immediately follow its encoding, but other information is acquired in the interval between encoding and retrieval of the same material. Indeed, learning different material in two different contexts confers a memory advantage over learning all the material in the same context. To sum up, learning different material in the same context impairs recall, due to interference, while the same context at encoding and retrieval enhances recall. This phenomenon, that is 'context dependency,' is well evident in a free recall experiment (Godden and Baddeley, 1975), in which divers learnt lists of words in two different environments: on the shore and underwater, and recalled the words in either the environment of original learning or in the alternative environment. Lists learnt underwater were best recalled underwater, and vice versa. Similarly, alcoholics may hide objects when drunk, forget where they have put it when sober, but remember it again in a subsequent binge; also lists of words learnt after having smoked marijuana were better recalled when these participants smoked again just before retrieval (Eich, 1980). Tulving (1983) has argued that the extent to which there is contextual similarity between the retrieval attempt and the initial encoding phase predicts the likelihood of remembering vs forgetting (the so-called encoding specificity hypothesis). Therefore, a crucial characteristic of episodic memory is that when an event is encoded, features of the physical environment are typically bound into the resulting episodic memory representation, providing an additional route to later recall. If these features will be in the environment at the time of retrieval, they will act as cues to memory and will help retrieval of further details of the event.

Neural Correlates of Encoding

The brain must not only encode the specific aspects of an event but also bind them in a manner that can later specify the spatiotemporal context in which the to-be-remembered event occurred. Converging evidence indicates that different regions of the medial temporal lobes may form representations of items, contexts, and item-context bindings and that areas in the dorsolateral prefrontal cortex are related to the processing of relationships between items. Indeed, the dorsolateral prefrontal cortex activity during encoding predicts subsequent memory specifically if participants are given encoding tasks that encourage relational processing or retrieval tests that are sensitive to memory for associations among items (Ranganath, 2010). Encoding requires in particular the activity of the left inferior prefrontal cortex, when deep encoding, that is semantic processing of verbal stimuli, is performed (Kapur et al., 1994). When visual learning is assessed, there is a greater engagement of the right frontal lobe (Brewer et al., 1998). This material-specific model of hemispheric asymmetry coexists with a process-specific model known as hemispheric encoding–retrieval asymmetry (HERA). According to the HERA, left prefrontal cortex is more involved than the right prefrontal cortex in episodic memory encoding, whereas the right prefrontal cortex is more involved than the left in episodic memory retrieval (Tulving et al., 1994).

The prefrontal activity also controls how attention is directed and coordinates posterior sensory cortices where components of an episode are represented. The prefrontal cortex seems also to represent the temporal features of an episode.

It appears therefore that the frontal lobes are heavily involved in episodic memory: an extensive discussion about the relation among episodic memory, autonoetic consciousness, and the frontal lobes can be found in Wheeler et al. (1997).

Consolidation

Memory changes with the passage of time after learning and after the initial registration of information, and a fraction of experienced episodes is permanently stored in the brain through consolidation, the maintenance of information over time. In sum, consolidation is the process that modifies the memory traces so that they become more stable over time: the memory is established in storage.

Memory consolidation is inferred from the existence of gradients of retrograde amnesia after damage to the brain, more specifically to parts of the medial temporal lobe: indeed, when the medial temporal lobe is damaged, old memories are in general better preserved than more recent ones. It is therefore assumed that damage interferes with some time-dependent process, which functions to make memory permanent. It is however not clear how long the period during which memory can be disrupted lasts before consolidation takes place. Following one view, early, fragile memory depends on the hippocampal system, located in the medial temporal lobe, while stable memory does not (Squire, 1992). Squire's 'standard model' of memory consolidation assumes that consolidation involves long-term interactions between hippocampal and extrahippocampal circuits. Originally, this model was intended to apply to explicit (declarative) forms of memory, including both semantic and episodic memory. The standard model supposes that the hippocampus plays a time-limited role in memory storage, either by first storing and then transferring a memory, or by acting as an index that binds extrahippocampal storage sites during a period when direct communication among these sites is inadequate to permit memory retrieval. These extrahippocampal sites then acquire the ability to interact such that the hippocampus is no longer required to retrieve memories. Nadel and Moscovitch (1997) challenged the assumption of a long-term consolidation processing strengthening neocortical neurons and resulting in the transfer of information initially stored in the hippocampal complex to the neocortex. They generated a new model called the 'multiple trace theory'; according to it, the hippocampal complex encodes all information that is attended or consciously apprehended and this information is sparsely encoded in a distributed ensemble of hippocampal neurons. Because the hippocampal complex encodes all information that is attended, each reactivation of a memory trace results in the creation of a newly encoded hippocampal trace, which again is sparse and distributed. By virtue of indexing a similar set of neocortical neurons encoding the features of the episode,

each trace shares some or all of the information about the initial episode. Therefore, episodic memory always depends upon the hippocampal complex and its provision of contextual information. As episodic memories age, they would either be forgotten or would have benefitted from the formation of multiple traces in the hippocampal complex and neocortex. Thus, older episodic memories would be associated with a greater number of traces. Retrieval would become easier as the number of traces, and the number of access routes to them, increase. Because memory traces are sparse and distributed, even minimal damage at any location in the hippocampal formation could affect acquisition, retention, and recovery of any single one of them. Newly acquired traces would be particularly vulnerable, but older memories, which are multiply represented, would be able to withstand the loss of more hippocampal complex tissue. As a result, partial damage to the hippocampal complex would affect remote episodic memory in relation to its age, producing a graded retrograde amnesia. Each time an episodic memory is retrieved a replicate trace is created within the hippocampal complex, spreading out the representation of that memory.

Retrieval

To remember a past event, information must be retrieved from episodic memory. Retrieval produces the subjective experience of consciously remembering the past. Episodic retrieval involves an interaction between a retrieval cue, self-generated or provided by the environment, and a memory trace, leading to the reconstruction of the aspects (some or all) of the past episode (Tulving, 1983). This interaction between the memory trace and the retrieval cue (and what follows) was termed 'ecphory' by Semon (Rugg and Wilding, 2000). Retrieval can take place through recall or recognition. Recall of episodic information is usually intentional and effortful, but it can occur unintentionally and automatically when a particular thought or perception triggers the recollection of an experience. Tulving argues that the same processes are involved in recall and recognition, although the particular retrieval cues are different, in recognition being copy cues, i.e., copies of the original stimuli. The memory trace, however, is not a static entity waiting for an appropriate cue. Rather, retrieved memories are the result of a complex interplay of stored information and retrieval cues.

Several factors influence whether an episodic retrieval attempt will be successful or not; one of such factors is the way in which the event was encoded, as mentioned above.

As reported, experiences such as remembering last birthday party or our first job interview represent unique events tied to a specific point in time and in space. The retrieval of this type of information is strongly influenced by the context within such episodes occurred, as the reported experiment on divers illustrates. However, a subsequent experiment on divers (Godden and Baddeley, 1980) using recognition instead of recall, found no significant context-dependency effect, and this is also confirmed with a wide range of drugs, including those used to anesthetize patients (Eich, 1980). This seems to suggest that recall and recognition are not the same processes, as Tulving proposed. It appears that the person's internal state helps to access the memory trace, but when the access is made easier by presenting an item for recognition, the initial search stage is not necessary.

In addition, results from cognitive, neuropsychological, and neuroimaging studies of human memory indicate that recognition memory performance reflects two distinct processes, referred as recollection and familiarity. Recollection is defined as the mental reinstatement of previous events and reflects the retrieval of qualitative information about a specific study episode, such as when or where an event took place, while familiarity reflects a more global measure of memory strength or stimulus recency without retrieval of any specific details about the study episode (Yonelinas et al., 2010). During recollection, unique details of a memory are recalled, which may include additional sensory information, such as the sounds paired with an event, or the emotions experienced during the initial encoding of it. In contrast, familiarity is a mental awareness, a subjective sense that an event has been experienced in the past, but the memory is lacking the unique details or mental reinstatement of the event that accompanies recollection. The difference between these two processes is easily demonstrated in everyday life by the example of meeting a person we recognize on the street. Sometimes we can specifically place where, or when, we had met her/him. This is a recollective process: we recognize an item on the basis of the retrieval of specific contextual details. In contrast, we sometimes strongly feel that we have met this person before, but cannot identify where or when we originally encountered her/him. The person is familiar, despite the fact that we cannot recollect unique details of the initial meeting. This is a familiarity process: a stimulus is matched against information in memory and if the stimulus and the stored information match or there is sufficient overlap, we find it familiar without having specific details. Several dual-process models have been developed to account for the observation that recognition memory judgments can be based on recollection or familiarity that have distinct modes of operation.

But how does a retrieval cue serve to bring back details about the past? Episodic memories are encoded by binding together the various features of a stimulus or event into an integrated representation, so an episodic memory consists in a conjunction of linked features. Any of these features is a potential route to memory and makes possible to have access to memories even when information is limited. When a retrieval cue – external or internal, namely provided by our own state – that corresponds to part of the encoded information finds a stored representation, other features bound to this representation are reactivated, reconstructing a whole from linked parts.

Neural Correlates of Retrieval

The distinction between familiarity and recollection has prompted a debate to define the role of the hippocampus and adjacent structures in recognition memory. Neuroimaging data have shown that in the hippocampus and the adjacent cortex, retrieval associated with recollection produces more activation than retrieval associated with familiarity (Eldridge et al., 2000), suggesting that this structure is more involved in recollection than in familiarity judgments or, alternatively, that a greater amount of information is retrieved during recollection

Figure 1 Prefrontal cortex and medial temporal lobe structures involved in episodic memory.

than familiarity judgments. In line with neuroimaging results, in patients with a damage to the hippocampal region, familiarity is as severely impaired as recollection (Manns et al., 2003). Apparently, both types of recognition memory depend on the integrity of structures within the medial temporal lobe, including the hippocampal region, but episodic recollection depends also on the frontal lobes (Shallice et al., 1994). Indeed, patients with frontal damage have difficulty in recollecting the details of earlier personal events. More specifically, the frontal lobes are important when we develop a strategy to retrieve, so that we select and represent the cues that can be used to reconstruct a memory. The frontal lobes also support mechanisms that resolve competition or interference between competing memories: more than one memory can be retrieved from a single cue and the memories compete to be fully retrieved. Interference during retrieval can produce forgetting and patients with frontal lesions are particularly prone to interference-based forgetting (Shimamura, 1995). Finally, the frontal lobes are important for evaluating or monitoring the quality and quantity of retrieved information (Figure 1).

There are, though, opposite views concerning the relative contribution of the hippocampus and the surrounding cortex to recollection and familiarity, since patients with hippocampal damage or dysfunction and a disproportionate deficit in recollection as compared to familiarity have been described (Vann et al., 2009). This is confirmed by neuroimaging studies (Ranganath et al., 2003), in which activity in the hippocampus and parahippocampal cortex during encoding was predictive of whether participants could subsequently recollect information about the context in which an item had been studied, but activity did not differentiate between missed items and items recognized on the basis of familiarity. In contrast, activity in the perirhinal cortex correlated with subsequent familiarity-based item recognition but was not sensitive to recollection. This suggests that the hippocampus and the perirhinal cortex subserve complementary encoding mechanisms that build representations that support recollection or familiarity, respectively.

Conclusion

Our episodic memory is capable of storing large amount of information and to make accurate retrieval. Retrieval depends on the type of encoding during the original experience, with context acting as a powerful recall cue. While retrieval can be relatively automatic, sometime recollection is similar to problem solving, since we have to follow our cues and check for the result of our search in order to reconstruct the whole episode. Future research, however, is still required to investigate several open issues, such as (1) the role of attention in deciding which aspects of an event will be treated as items and which as context, (2) the relative role of the hippocampus and adjacent cortex in storage as compared to retrieval, but also in familiarity, (3) the precise role of the posterior and frontal neocortices and the medial temporal lobe in encoding, storing, and retrieval of episodes, (4) how specific aspects of an event are processed and then bound together and inserted into a temporospatial context, and, finally, (5) the relation between semantic and episodic memory and how semantic memory contributes to episodic encoding.

Epistemic Communities and Collaborative Research

Morgan Meyer, Agro ParisTech, Paris, France

Abstract

This article discusses epistemic communities and collaborative research. The first part reviews the genealogy and the definition of the concept of epistemic community and, thereafter, the various developments and criticisms of the term. The second part looks at various forms of research collaborations between scientists, with stakeholders, and with laypersons. The two terms are abundant not only in capturing the ways in which actors work together in order to produce and publicize knowledge, but also to reveal how knowledge is entangled with politics, economics, and social issues.

Introduction

Today, decisions are increasingly based on expertise and scientific knowledge. When governments, for instance, take actions regarding health issues, telecommunications, the environment, or the economy, they usually call on experts to guide them and to provide a knowledge base for solving issues. But these experts are hardly ever just individual persons conveying their personal opinions. Experts are members of wider networks and communities, which are usually international and interdisciplinary in outlook. The Intergovernmental Panel on Climate Change or the Delors Committee, which wrote the blueprint for the European Economic and Monetary Union, are but two examples of such 'epistemic communities.' Epistemic communities play an increasingly important role in communicating knowledge, in defining international problems, and in shaping policies.

However, to clarify what we mean by communities, we need to focus not only on communities per se, but also on 'collaborative research.' The increase in collaborative research, and the shift from 'little science' to 'big science,' has been documented both in the history of science and through scientometric studies. (It is the science of measuring and analyzing science. See also the journal, *Scientometrics*, which has published numerous articles on collaboration.) In addition, there are now many cases in which we also observe research collaborations across and beyond communities (for example with industry). Such collaborations bring together not only researchers, but also stakeholders and even laypersons, and show that knowledge is frequently produced across institutional and cognitive boundaries.

Epistemic Communities: Genealogy and Definition of the Concept

The attention to epistemic communities has a relatively long tradition in the social sciences, predating the increasing prominence of the term since the 1990s. An early author concerned with both knowledge and the communal aspects of knowledge production and circulation is Ludwig Fleck via his notion of 'thought collectives' (1935). Fleck defined thought collectives as a "community of persons mutually exchanging ideas or maintaining intellectual interaction," and he used the term specifically to refer to scientists. In line with Fleck's view, Thomas Kuhn later coined the notion of 'paradigms' (Kuhn, 1962), arguing that any member of a scientific community needs to accept and work within a given paradigm. Paradigms – defined by Kuhn as "universally recognized scientific achievements that, for a time, provide model problems and solutions for a community of practitioners" – are most visibly revealed in the textbooks, lectures, and laboratory exercises of a scientific community. A paradigm defines both what counts as knowledge and who counts as a legitimate member of a knowledge community.

The first group of authors to use the term 'epistemic communities,' and develop it through the 1960s and 1970s, is Holzner and his coauthors (Holzner, 1968; Holzner and Salmon-Cox, 1977; Holzner and Marx, 1979). In their body of work, epistemic communities are conceptualized as communities for whom 'epistemic criteria' have primacy over other interests. What members of epistemic communities have in common is their faith in scientific methods to produce truth. While the influence of the work of Holzner and his coauthors has been relatively modest, the term 'epistemic community' was forcefully reintroduced in the early 1990s. Two authors from the global policy/relations tradition, Adler and Haas (Adler, 1992; Adler and Haas, 1992; Haas, 1992) paved the way for an increasing amount of studies on such communities. According to them, an epistemic community is "a network of professionals with recognised expertise and competence in a particular domain and an authoritative claim to policy-relevant knowledge" (Haas, 1992, p. 3). Epistemic communities, so the often-quoted definition reads, are defined as:

> (1) a shared set of normative and principled beliefs which provide a value-based rationale for the social action of community members; (2) shared causal beliefs, […] which then serve as the basis for elucidating the multiples linkages between possible policy actions and desired outcomes; (3) shared notions of validity – that is, intersubjective, internally defined criteria for weighting and validating knowledge in the domain of their expertise; and (4) a common policy enterprise – that is, a set of common practices associated with a set of problems to which their professional competence is directed, […].
>
> Haas, 1992, p. 3

This definition of epistemic communities builds on what both Fleck and Kuhn defined as 'thought collectives' and

'paradigms.' Haas and Adler's work on epistemic communities can thus be seen as a continuation of the tradition in the social sciences to provide a theoretical and analytical tool to understand collective knowledge production. However, the object of study has shifted: the key focus is no longer only on scientific communities alone, but on how experts influence policy decisions. An example discussed by Haas is the epistemic community that brought about policy change in the field of chlorofluorocarbons (CFCs): the Montreal Protocol which led to a phasing out of components containing CFCs, can arguably be attributed to the work and efforts of an international epistemic community.

Developments and Criticisms

Expanding Analytical Frameworks

Epistemic communities have initially been studied through their links with the world of policy-making: for example, effects of epistemic communities on, and implication with, waste management, environmental, or multinational policies (e.g., Verdun, 1999; Zito, 2001). Over the years, the framework for studies has expanded to include business enterprises (Håkanson, 2010; Gittelman, 2007), social movements (Dobusch and Quack, 2010), open source (Cohendet et al., 2001; Edwards, 2001), higher education (Choi, 2014), scientific disciplines (Ahlgren et al., 2013), and national/international security (Cross, 2011). The concept of epistemic communities is now used in a variety of academic fields: political science and international relations, economics, law, business studies, public administration, sociology, history, organization and management studies.

Epistemic communities are usually not limited to a specific location or site, but can consist of people in different countries and with various professional backgrounds. The usefulness of the notion is evident in the body of work that has drawn on the framework set out by Haas and Adler. By focusing their research on epistemic communities, scholars are thus able to provide an analysis that connects knowledge, collectivity, and policy. These interconnections are studied at various scales, times, and in different political and cultural contexts. Another advantage is that the various dynamics and effects of epistemic communities are accounted for not only dealing with knowledge creation and propagation but also concerned with the consequent decisions and actions, as the knowledge they produce and share usually leads to policy actions and institutional change.

Criticisms of the Concept of Epistemic Communities

Nonetheless, several points of criticisms have been raised about the definitions of epistemic communities.

- First, a too narrow focus on the knowledge and characteristics that epistemic communities share might overstate the formation of consensus and collective knowledge. Conversely, some definitions may not reflect the disagreements, tensions, and uncertainties that are evident among communities.
- Second, the assumed impact of epistemic communities and their ability in solving problems in the policy domain has often been taken for granted, and is sometimes not looked into in depth. It must be stressed that governments will hardly follow epistemic communities' claims if they diverge too much from their own interests. A precondition for the knowledge claims of epistemic communities is that policy actors are willing to listen to, accept, and act upon their knowledge.
- Third, the concept has above all been used to discuss scientists and scientific knowledge. But there are many other actors, such as diplomats or lawyers, who can form epistemic communities that are not necessarily based on scientific knowledge. Even though Adler and Haas explicitly state that the 'epistemic' in epistemic communities should not only be limited to scientific knowledge, most studies have nevertheless done so.
- Fourth, the formation and constitution of epistemic communities has not been analyzed much. Epistemic communities seldom just pop up. They usually form in response to a problem or controversy that allows them to be established, funded, and given the mission and legitimacy to produce and publish knowledge. In addition, the dissolution of epistemic communities needs to be addressed – whether it is due to their fragmentation, the fact that the policy issue they were meant to address was resolved, or due to other reasons.

The above points should be addressed – and have been discussed to some extent – in order to consolidate, broaden, and rethink the concept of epistemic communities. In particular, the emphasis on policy relevance and policy impact which has dominated the literature on epistemic communities should be reconciled with more anthropological and sociological readings of the term. Epistemic communities, in this view, provide a rich topic to examine: how communities produce and act with knowledge (i.e., how they communicate, distribute, accumulate, and store knowledge); how communities are constituted and stabilized; how they change over time and articulate their own histories and futures; how they differ in terms of their policy effects and in terms of the strength of their internal ties; and how they shape, demarcate, and negotiate the identities of their members and their collective identity more generally (see Meyer and Molyneux-Hodgson, 2010).

Collaborative Research

While collaborative research, unlike 'epistemic communities,' has not been extensively theorized and defined, examples of collaborative research nonetheless proliferate. Collaborative research can be understood along a continuum of different forms and formats. On the one side, there are research efforts that bring together scientists among the same scientific discipline. On the other side, there are research efforts that bring together scientists and laypeople which is where collaborative efforts cut across the boundaries of academic institutions. Between these two poles, we can observe collaborations involving researchers with various disciplinary backgrounds, for example, in interdisciplinary and multidisciplinary research endeavors, or involving researchers and other actors, e.g., medical practitioners, decision-makers, or industrial partners.

Collaborations between Scientists

Collaborations raise several important questions, including the trust and tensions between collaborators, the required efforts for coordinating and aligning work, and its effects on scientific productivity (see for instance, the special issue on scientific collaboration in the journal, *Social Studies of Science* (2005: 35 (5)); Davenport et al., 1998; and Shrum et al., 2007). One could argue, of course, that there is no such a thing as 'noncollaborative' research. Research is by its nature a collective and social practice. Whether doing or supervising a PhD, participating in a research project, writing and reviewing academic papers, authoring texts and reports, building and using equipment, or exchanging ideas and criticisms, researchers hardly work on their own when carrying out their activities. Having said this, it is necessary to stress the collaborative nature of knowledge production, particularly in scientific fields in which collaborative research is common practice (e.g., physics or biology) as opposed to fields where it is much rarer such as the humanities. One example, in the field of particle physics, is the European Organization for Nuclear Research (CERN) based in Geneva, Switzerland. Involving around 30 countries, several thousand employees, 600 universities and research facilities, the CERN is arguably the most iconic example of a research collaboration. Research papers from the CERN usually have several hundreds of authors. The current record of number of authors of a single research paper is just above 3000. Other large-scale collaborations include: the Human Genome Project, an international project completed in 2003 to sequence the human genome; the Human Brain Project, a project launched in 2013 to bring together the neurosciences, medicine, and computer science to better understand the human brain; and the numerous telescopes built in the desert of Atacama in Chile and financed by various countries since the 1970s.

A frequently shared assumption is that collaborations such as the Human Genome Project or the various experiments carried out at CERN are essentially unbiased and politically neutral. Especially their international setup and the large cohort of collaborating institutions and universities are seen as proof that science knowledge production is neutral. Yet, it is not only the complexity of experimental procedures, the interdisciplinary nature of scientific problems, and the high cost of some technical equipment that call for collaborative work. Numerous studies have shown that collaborations are inevitably shaped by wider historical, social, political, economic, and/or military issues (e.g., Parker et al., 2012; Knorr-Cetina, 1999). The Manhattan project, responsible for developing the atomic bomb during World War II, is an illustration of the entanglements of researchers and the military complex. The Human Genome Project raised economic questions (as it was rivaled by a similar project led by a private company) and called for the need to reflect on the ethical, legal, and social issues inherent in the project. Moreover, studies of the field of high-energy physics show that gender and power issues are frequent among science communities (Traweek, 1992). In general, debates and controversies about power, authorship, and ownership are frequent in large collaborations, as are disputes about the primacy and prestige about some scientific fields over others.

Collaborations with Laypersons

There are many examples of collaborations between amateurs and professional scientists: in the fields of natural history, astronomy, epidemiology, medicine, biology, environmental science, or informatics. In natural history, for instance, there is a long tradition of amateurs doing fieldwork and producing knowledge together with professionals (Star and Griesemer, 1989). These amateurs do often collaborate to produce maps, to feed databases, or to coorganize educational or museological activities. In the fields of medicine and epidemiology, there are also a number of examples: AIDS treatment activists have been involved in the production and evaluation of biomedical knowledge (Epstein, 1996), and there are patient associations that are actively engaged in scientific research and collaboration with professionals (Callon and Rabeharisoa, 2003). Thus, these actors challenge the assumption that only scientists or experts can engage in research practices and produce reliable knowledge. It shows that there are indeed areas in which the production of knowledge is based on collaborative work that spans across the boundaries of traditional knowledge communities, and that users, amateurs, or patients can play an active role. While this form of collaboration is sometimes called 'collaborative research,' there is a plethora of other terms used in the academic literature such as 'co-production,' 'participatory research,' or 'community-based research.'

The benefits of such collaborative research efforts are epistemic. Science can become more accessible and democratic by involving target groups or laypeople, and researchers have access to much bigger data sets and computer power. On the other hand, there are also nonepistemic driving forces. In the field of ecology and natural history, the ultimate aim is usually a better understanding and protection of the natural world. In epidemiology and medicine, laypeople often try to change research priorities and focus on health problems that are not funded and not visible in the public domain, and they sometimes go against established norms. As for the do-it-yourself biology movement or the hacker movement, they are providing alternative, experimental spaces accessible to various people and interests, they are developing workarounds around standardized technical equipment and protocols, and they are portraying themselves as an alternative to mainstream science. All in all, collaborative research involving laypeople seeks to address, in some form or another, ecological, health-related, or political issues that mainstream academic science does not or cannot deal with.

Collaborations with Stakeholders

As with laypeople, there are a number of examples of collaborative research efforts where researchers cooperate with various stakeholders, which include collaborations with decision-makers or collaborations with industries (such as the computer or the nuclear industry). Collaborations among researchers and medical practitioners, in particular, have become prominent in recent years. Translational medicine, a well-documented example, has been hailed as a new 'paradigm,' and one of the most important developments in medicine since the beginning of the twenty-first century. The essential idea of translational medicine is to create links

between basic research and clinical research, between researchers working in a laboratory and patients and doctors in a hospital (see Martin et al., 2008 and the special issue of the journal, *Tecnoscienzia* on the topic (2014: 5 (1))). The common slogan is to move 'from bench to bedside' because current links between laboratories and hospitals are deemed problematic. The links are seen as too time-consuming (it takes many years from the discovery of a new molecule or therapy to its use), too difficult (several disciplines, institutions, and professions need to collaborate and coordinate their efforts), and too expensive (the development of a molecule costs millions of euros and only about 5% of new molecules eventually become marketable products.) This is why political and academic actors are actively fostering translational medicine by establishing centers of translational research to help scientists collaborate with doctors and to translate knowledge from the laboratory into applicable innovations and products. An institutionalization and formalization of new kinds of collaborations is currently under way via the creation of new institutions, journals, networks, posts, and platforms dedicated to translational medicine.

This does not mean, however, that collaborations between researchers and hospitals now happen without any friction. Collaborations often reveal important discontinuities – which can be disciplinary, organizational, linguistic, cultural, ethical, and political – between biology and medicine. Translational medicine is sometimes described as being 'lost in translation' due to several barriers: the difficulty of moving from a model (animal, *in vitro*) to humans; the fact that diseases are not simple, but heterogeneous and complex objects; the presence of different ethical and practical norms; language and cultural barriers; the incompatibility of databases and samples; the lack of qualified people and of support. Research laboratories and hospitals are spaces with their own temporality and sociality, and they embody different regimes of knowledge production and knowledge use. The same counts for the case of partnerships between universities and industry, and between universities and policy-makers: the temporal, social, and cultural differences between these worlds might pose a challenge for collaborative research. In the case of university–industry linkages, issues about intellectual property, secrecy, patents, and academic freedom become particularly salient (a topic frequently covered in the journal, *Research Policy*). As for collaborations between universities and policy-makers, debates often focus on the applicability, usability, and relevance of academic knowledge and the position of experts (as opposed to scientists).

Concluding Remarks

In the social sciences, the term community has been used so ubiquitously that it almost went out of fashion. The term seems to have lost any precise meaning, and the amount of interdisciplinary and transdisciplinary research work has made the term 'discipline' seem old-fashioned. However, professionals and scientists still carry out research through (epistemic) communities, and despite collaborations across disciplines, this still has impacts on teaching, shaping identities, and organizing research work.

The success of the term epistemic community both as a theoretical framework, and as a tool for analyzing the relationships between knowledge and policy proves that the term community can be reinvigorated. Rather than doing away with the concept of community, the way forward is to raise new questions in order to examine the ways in which communities establish expertise, share beliefs, respond to policy issues, act on a global scale, and lead to change. As for the term collaborative research, it serves as a forceful reminder that research work is, by essence, a collaborative endeavor and that the variety of formats and practices of collaboration is the norm, and not the exception in science. And while the rise, diversity and challenges of collaborative research has now been relatively well documented, there still are exciting research avenues calling for further academic studies. The role of new collaborative tools such as crowdfunding, online file sharing systems, wikis, and communication technologies in shaping knowledge production are only beginning to be examined. Moreover, new opportunities have arisen concerning collaborations between the social sciences and the natural sciences. The benefits and drawbacks of being an embedded social scientist – for instance, in the fields of nanotechnology and synthetic biology – call for more academic work. (Embedded social scientists do not only analyze the work done by natural scientists but they closely work with them: they often share research funding, become integrated in interdisciplinary research teams, and are responsible to address the social and ethical issues of scientific research.) The recent Manifesto for Experimental Collaborations between Social and Natural Scientists (Balmer et al., 2012) proves that collaboration continues to be a challenging topic.

The two terms reviewed in this article are effective tools to not only capture the ways in which actors work together to produce and publicize knowledge, but also to reveal how knowledge is entangled with politics, economics, and social issues.

Abstract

Studies of epistemic communities and collaborative research in the social sciences have deepened the understanding of how science works, and more specifically how the social dimensions of scientific practice both enable and impede social scientists in realizing their epistemic goals. Two types of studies of epistemic communities are distinguished; general theories of epistemic communities aim to construct accounts of theoretical change applicable to all social scientific specialties, whereas historical studies emphasize the contingencies that affect specific social scientific disciplines, subfields, or institutions. Although collaborative research plays a less pronounced role in the social sciences than in the natural sciences, collaboration has enabled social scientists to investigate topics that would otherwise be difficult to investigate.

The Structure of Epistemic Communities

Research Communities

An epistemic community is a network of knowledge-specific experts who are able to generate, and verify knowledge claims. Epistemic communities exist in the social, as well as the natural sciences. Epistemic communities and their structure affect social scientists' prospects of realizing their epistemic goals. The practices surrounding collaborative research influence how research is done as well as what research is pursued.

The most important type of epistemic community in the social sciences is the specialty community, the collection of social scientists working in the same subject area. Those in a specialty community are tied together by research interests, standards, practices, shared background assumptions, and often conceptual frameworks. The structure and development of epistemic communities in the social sciences has been studied mainly by sociologists.

In *Structure of Scientific Revolutions*, Thomas Kuhn (1962/2012) suggests that in mature scientific fields the only people qualified to evaluate research contributions are other members of the research community. By the time a field has reached maturity, the research literature is quite technical, and those contributing to the literature assume a high level of mastery of the subject matter. Kuhn's theory of scientific change was developed in response to his study of the history of the natural sciences. But it does seem that research in the social sciences is developed and written principally for other specialists. Consequently, it should not be surprising if outsiders, lay people and even scientists working in other social scientific fields, are unable to comprehend the latest research in a field. Some, however, claim that the social sciences differ fundamentally from the natural sciences in this respect, given that the objects of study in the social sciences are people and institutions that are familiar to the lay person. But this is misleading. Social scientists have developed and continue to develop technical vocabularies for the phenomena they study. And even when social scientists use familiar terms, they often use these terms in very precise and technical ways that may not reflect the lay person's understanding (see Durkheim, 1951: pp. 41–42).

Communication Networks

Research communities are not only arbiters of research quality, determining who gets funding and what research gets published, they also provide an infrastructure through which scientists are able to advance their research goals, reaching out to other researchers. Diana Crane (1972) argues that epistemic communities are united by 'invisible colleges,' informal communication networks facilitating the fast and efficient transfer of information across the research community. Not all researchers, however, are connected with the invisible college in their field. Crane found that those who are not well connected tend to be less productive than their peers who are connected.

There is some evidence that the communication networks in research communities are held together by the collaborative networks (Newman, 2001: p. 407). M.E.J. Newman found that in a number of research communities, between 80 and 90% of all authors are connected to each other through collaborative relationships. Some of the chains connecting any two scientists in such a network can be quite lengthy, but Newman suggests that these relationships probably facilitate communication in science.

'Epistemic Communities' as a Technical Term in International Relations

It is worth noting that the term 'epistemic communities' has acquired a very specific meaning in the subfield of international relations. It has become a technical term in this context. Some political scientists believe that the term is useful for picking out a new type of player or agent in international policy debates (see Haas, 1992). In this context, epistemic communities are groups of experts consulted by governments and other parties involved in political debates. The members of an epistemic community are bound together by "a shared set of normative and principled beliefs … shared causal beliefs … shared notions of validity … and … a common policy enterprise" (Haas, 1992: p. 3). These groups have "recognized expertise and competence in a particular domain and an authoritative claim to policy-relevant knowledge within that domain" (Haas, 1992: p. 3). And, other groups that are involved in such

debates aim to secure a specific outcome that supports the interests of their own group; whereas, when epistemic communities are concerned, that policy will be directed by knowledge. The point of invoking these new 'agents' in analyses of international policy debates is to account for how international policy decisions are actually made. "The epistemic communities approach focuses on [the] process through which consensus is reached within a given domain of expertise and through which the consensus knowledge is diffused … by other actors" (Haas, 1992: p. 23). The traditional list of agents in international policy debates – nation states, politicians, bureaucrats, and bureaucratic entities – provides an incomplete picture. Political scientists employing the term 'epistemic communities' in their analyses represent a particular theoretical orientation in the subfield of international relations. Their influence, although noteworthy, is relatively isolated.

Epistemic Communities: Social Sciences and Natural Sciences Compared

Consensus

Much of the understanding of epistemic communities in the social sciences is a result of comparisons with epistemic communities in the natural sciences. Kuhn (1962/2012) argues that in the natural sciences, unlike the social sciences, researchers agree upon the fundamentals. That is, researchers working in a particular field in the natural sciences accept the same theoretical framework and methodologies. Epistemic communities in the natural science are thus unified to a great extent. In the social sciences, on the other hand, researchers often work from competing theoretical frameworks. Originally, Kuhn expressed this point in terms of paradigms. The researchers in subfields in the natural sciences share a paradigm, whereas researchers in the social sciences lack paradigms. Although this generalization may not apply across all areas of research in the social sciences, there does appear to be far less consensus about core knowledge in the social sciences than in the natural sciences, where core knowledge is understood to be the settled accepted beliefs in a field.

Textbooks

The broad consensus that characterizes epistemic communities in the natural sciences is reflected in the content of textbooks. Competing textbooks in the natural sciences do not present competing theories. In the natural sciences, young scientists-in-training are taught the accepted theories only. The social sciences are different. In sociology, for example, it is not uncommon for an introductory textbook to present competing theoretical frameworks: the structural–functional paradigm; the social-conflict paradigm; and the symbolic-interaction paradigm (see, for example, Macionis, 1997; see also Lavirière et al., 2006: p. 521). Indeed, the same phenomenon, crime, for example, may be examined through the lenses of all three sociological paradigms. Young sociologists-in-training thus learn from the beginning of their training that their field is divided with respect to theoretical orientation. Stephen Cole (1992) notes some important differences with respect to the sources cited in textbooks in the natural sciences and in textbooks in the social sciences. First, in the natural sciences, textbooks tend to cite older research. Sociology textbooks, on the other hand, predominantly cite recent research. Second, natural science textbooks focus on the core knowledge in a field, whereas textbooks in the social sciences focus more on the research frontier. The research frontier is where scientists are currently conducting research, and where investigations are unresolved. Cole suggests that this difference between textbooks in the natural sciences and textbooks in the social sciences may be due to the fact that the core knowledge is smaller in the social sciences than in the natural sciences (see Cole, 1992: p. 131). He also found that, although the natural sciences and the social sciences differ with respect to core knowledge, there is little difference at the research frontier. Natural scientists and social scientists are equally divided about issues at the research frontier. This is evident from the fact that in both the social sciences and the natural sciences there is little agreement about the value or worthiness of grant proposals (Cole, 1992: p. 123).

Publications

There are also significant differences between social scientists and natural scientists with respect to publication patterns. In a recent study of the various publications in journals indexed in the *Web of Science*, Lavirière et al. (2006) found that 72% of the publications of natural scientists are articles. The remaining publications are principally meeting abstracts, letters, notes, and review articles. In contrast, only about 59% of the publications by social scientists are articles. And, less than 0.1% of the publications of natural scientists are book reviews, whereas 27% of the publications by social scientists are book reviews. Lavirière et al. (2006) take this last difference to indicate the relative importance of books in the social sciences. Although the scholarly book is now obsolete in the natural sciences, books are still an integral part of scholarship in the social sciences.

Collaborative Research

Collaborative Research in the Natural and Social Sciences

Collaborative research is a vital part of epistemic communities and can be carried out in different ways. Collaborative research is ubiquitous in the natural sciences. In some fields, more than 85% of the publications are multiauthored (see Zuckerman and Merton, 1973). Knorr-Cetina (1999) has compared the publication and research practices in two scientific cultures where collaboration is common, the culture of high energy physics (HEP) and the culture of molecular biology. Knorr-Cetina found that the two cultures differ significantly in important ways. Research in HEP is conducted at large research institutions, like the European Center for Nuclear Research, and such research is frequently reported in articles authored by many scientists. A single article may be coauthored by 50 or more scientists (see Thagard, 1999: p. 169). Research in molecular biology, on the other hand, is done by smaller teams, and as a result articles have far fewer coauthors.

Table 1 Percentage of articles that are coauthored, by decade and area

Years	*Natural sciences (%)*	*Social sciences (%)*	*Humanities (%)*
1920–29	49	6	1
1930–39	56	11	2
1940–49	66	16	1
1950–59	83	32	2

Adapted from Zuckerman, H., Merton, R.K., 1973. Age, aging, and age structure in science. In: Merton, R.K. (Ed.), The Sociology of Science: Theoretical and Empirical Investigations, Edited and with an Introduction by N.W. Storer. University of Chicago Press, Chicago, pp. 497–559.

The research cultures in the various social sciences also differ from each other. Although collaboration has become more popular in the social sciences, the single-authored article is still the norm in many fields. Zuckerman and Merton (1973) provide data on the differences between the percentage of papers that are multiauthored in the natural sciences, the social sciences, and the humanities. These data are drawn from a sample of key journals in various fields (adapted from Zuckerman and Merton (1973): p. 547, Table 7) (see **Table 1**).

The data in **Table 1** take one to the end of the 1950s. Lavirière et al. (2006) provide more recent data on the prevalence of collaborative research. Their data are from the following Thomson Scientific databases: the *Science Citation Index*, the *Social Sciences Citation Index*, and the *Arts & Humanities Citation Index* (Lavirière et al., 2006: p. 523). See **Table 2**.

Researchers in the social sciences collaborate less than researchers in the natural sciences, but significantly more than researchers in the humanities.

International Collaboration

It is also worth noting that social scientists collaborate with researchers from other countries at half the rate that natural scientists do. About 20% of all the articles published in the natural sciences involve international collaboration, whereas only about 10% of all the articles published in the social sciences involve international collaboration (Lavirière et al., 2006: p. 526). Levels of international collaboration also vary from country to country. In China, South Korea, and Belgium, for example, social scientists are about four times more likely to collaborate with scholars from other nations than are social scientists in the United States (Lavirière et al., 2006: p. 527; see the Footnote on page 525). In a study of articles published between 1984 and 1994 in 13 key social science journals, James Endersby reports that about 54% of articles are coauthored (see Endersby, 1996: p. 382, Note 7).

Table 2 Percentage of articles that are coauthored, by decade and area

Year	*Natural sciences (%)*	*Social sciences (%)*	*Humanities (%)*
1980	76.3	28.4	5.4
1985	80.3	38.4	6.5
1990	84.6	43.6	6.9
1995	87.5	48.1	8.2
2000	89.3	54.1	8.1

Endersby also found that "the mean number of authors per article is 1.78" (p. 382, Note 7). Thus, very few articles in the social sciences are produced by large research teams. In fact, only 1 of the 13 journals had more than 3% of its published articles authored by teams of four or more, the *Journal of Personality and Social Psychology*. Indeed, collaboration is more common in social psychology than in other social sciences (see Endersby, 1996: Table 3 on page 383). There have been a few studies of collaborative research in specific disciplines in the social sciences. John Hudson (1996), for example, examines the changing trends in collaborative research in economics, drawing data from eight of the leading English language economics journals. Hudson looks at data from 1950 to 1993. Hudson found that between 1950 and 1965, "the *highest* proportion of multi-authored articles for any of the eight journals was 15.6 percent" (p. 154; emphasis added). In contrast, between 1974 and 1993 the *lowest* proportion of multiauthored articles for any of the eight journals was 35.5% (p. 154). Clearly, there has been a significant shift in the research culture in economics.

Reasons for Increasing Collaboration

Hudson (1996) believes that three factors contributed to the increase in collaborative research between 1950 and 1993. First, Hudson notes that there was significant "growth in the subject areas covered by economics" (p. 155). Second, he notes that economics became increasingly more technical. These two considerations force economists to work collaboratively. Unless they work collaboratively, there are many things they would be unable to study effectively, or at least unable to study effectively in a timely fashion. The third factor Hudson identifies as contributing to the increase in collaborative research in economics is the sheer growth of the profession. There are now significantly more economists, and thus significantly more researchers with whom one can collaborate (p. 155). Knowing that one can draw on the skills and conceptual and material resources of one's colleagues may lead one to think of research projects that would otherwise be inconceivable, or at least impractical. This third factor, rather than forcing collaboration on economists, provides an incentive to collaborate. Hudson notes that collaborative research in economics is more popular in quantitative studies than in qualitative studies. In fact, in *Economic History Review*, a journal that publishes primarily qualitative studies, fewer than 15% of the papers are multiauthored (1996: pp. 155–156). Importantly, Hudson recognizes that there may in fact be costs to this change in research practices in economics. For example, working as part of a team, individual economists may have to suppress their more radical and creative ideas, thus stifling the creativity of the field as a whole (1996: p. 157). Economics is not the only discipline in the social sciences in which collaboration has been studied. James Moody (2004) examines the changing trends in collaborative research in publications indexed in *Sociological Abstracts* between 1975 and 1999. He found that there was an increase in coauthorship from 31% in the period from 1975 to 1985, to 38% for the period from 1989 to 1999 (Moody, 2004: p. 221). He also found an increase in the number of authors involved in coauthored papers from an average of 2.4 authors in the

period from 1975 to 1985, to an average of 2.7 authors in the period from 1989 to 1999. Like Hudson, Moody found that in those subfields where quantitative studies are more popular than qualitative studies, collaboration is also more popular (2004: p. 214). Collaborative research is more popular in the sociology of medicine, the sociology of the family, and social psychology, areas that draw on "large datasets and [that require] cumbersome analyses that lend themselves to a substantive division of labor" (p. 223). In contrast, there is little collaboration in political sociology, the sociology of knowledge, and the sociology of science, where sociologists seldom work with large data sets (p. 223). In fact, Moody found that "those writing quantitative papers are over 5 times more likely to have coauthors than someone who has not written quantitative work" (p. 226). Moody also found that the collaborative practices in sociology give rise to a complex collaboration network. This network "is *not* held together by a small number of network stars," nor is the network "composed of distinct, separate clusters" (p. 228). Instead, Moody discovered that the network in sociology connects "people … from widely different specialties" (p. 228). Moody suggests that, as a consequence, sociology as a discipline has "permeable theoretical boundaries" (p. 228). Concepts developed in one specialty are readily adopted in neighboring specialties. Paul Thagard (1999) notes that scientists collaborate for many different reasons: (1) collaborative research can aid a scientist in teaching or mentoring scientists-in-training; (2) collaboration enables one to get a research project done more quickly; (3) collaboration enables scientists to collect together a set of skills and knowledge no single individual scientist has; and (4) collaborative research enables scientists to draw on conceptual and methodological resources in numerous fields (see Thagard, 1999: p. 170). These same reasons probably influence social scientists in deciding whether to become involved in collaborative research projects.

Interdisciplinary Collaborations

Often collaborative research projects involve social scientists in the same field, each bringing to the research project a different set of skills and knowledge. But sometimes social scientists from different fields collaborate. For example, economists and psychologists sometimes collaborate (Kahneman et al., 1990 is an influential example of such a collaboration). Sometimes social scientists are involved in collaborative research projects with natural scientists or medical researchers. These sorts of collaborations lead to special challenges including finding or creating a vocabulary that both collaborators can comprehend. Trostle and Sommerfeld (1996) provide a summary of the various projects and challenges at the intersection of medical anthropology and epidemiology. What is striking about this body of research is that the social scientists and the medical scientists involved are principally collaborating on applied projects, specifically, projects related to public health. The possibility of such collaborations has not been left to chance. In fact, by 1996 "at least 19 anthropologists [were] employed at the Centers for Disease Control and Prevention (CDC) … the central epidemiological research agency for the US federal government" (p. 255). Trostle and Sommerfeld believe that this body of research shows that the borders between disciplines are permeable (1996: p. 254). Importantly, some of this research helps scientists better understand key assumptions in their research. For example, "anthropologists working in epidemiological settings have published important critiques of racial classifications within public health statistics" (p. 259). Clearly, there are opportunities for social scientists to make similar contributions when they collaborate with scientists in other fields as well.

General Theories of Conceptual Innovation and Change in the Social Sciences

In addition to studying the structure of research communities, sociologists of science have developed theories of conceptual innovation and change in the social sciences. Randall Collins (1998) has developed a general theory of intellectual change in which he argues that "intellectual creativity is concentrated in chains of personal contacts, passing emotional energy and cultural capital from generation to generation" (p. 379). He also argues that "creativity moves by oppositions" (p. 379). Specifically, Collins claims that "new ideas unfold by negating the major points of rival positions in a shared topic" (p. 379). He also notes that there is a limit to how many competing schools of thought can exist at one time. His careful study of a number of examples of intellectual change drawn from history reveals that between three and six competing schools are sustainable at any one time in a field (p. 380). Collins intends his theory of intellectual change to apply to many different intellectual fields, and across cultures, and he provides evidence in support of his account from China, India, Japan, and Europe.

Andrew Abbott (2001) has developed an alternative account of conceptual change in the social sciences. Like Collins, Abbott believes there is an inner logic that leads to developments in the social sciences, a logic that is not found in the natural sciences. According to Abbott, new research areas and methodological approaches are created in the social sciences through a fractallike process. Sociology, for example, is often dominated by either a consensus paradigm or a conflict paradigm (pp. 17–18). A consensus paradigm takes consensus as the natural state of human groups, and the problem is to explain how conflicts arise. A conflict paradigm, on the other hand, assumes that conflict is the natural state of human groups, and the problem is to explain how consensus is achieved. According to Abbott, when the consensus paradigm is in ascendancy, inevitably some of the issues that the conflict paradigm treats adequately will be taken up by sociologists working in the consensus paradigm. Thus, epistemic communities are divided, with some researchers working in a thoroughgoing consensus paradigm, and others developing an alternative view that imports concepts and methods previously used by those working in a conflict paradigm. Social scientists are thus frequently reinventing old theories and concepts. But with each successive reinvention, social scientists are led to new insights.

Although their accounts of intellectual change differ in detail, both Collins and Abbott believe that a general account of intellectual change is possible. In this respect, their work is

continuous with traditional sociology of science, aspiring to develop a general theory.

Historical Studies of Epistemic Communities and Conceptual Change

Local and National Focus and Consumption

In contrast to the general theories mentioned above, historical studies of social sciences tend to emphasize unique contingencies that affect the development of disciplines and the institutions that support them. Such studies make no attempt to generalize from the particular cases they examine.

Historical studies of epistemic communities in the social sciences are an effective means to appreciate the contingency of the contemporary organization of the social sciences. Histories of specific institutions reveal even more contingency and variability. Michel Foucault's influential work reminds us of the complicated relationships between the social sciences and political power and social control (see, for example, Foucault, 1990). Social scientists are often called upon by others outside of the academic world for assistance, and this has shaped various epistemic communities as they respond to external pressures and incentives. The effective marketing of products, for example, draws on research in the psychology of perception. And the way social workers interact with the populations they serve is shaped by recent social scientific research. Immigrant women, for example, are treated differently as social scientists learn more about them (see Hacking, 1999, Chapters 4 and 5). Foucault suggests that because the knowledge generated by social scientists enables political states to have far-reaching control over their citizens' lives, social scientists can find themselves complicit in aiding political states in oppressing people. Clearly, this is not a problem unique to the social sciences. The workforce in the natural sciences has also been harnessed by those in power. Nuclear weapons, for example, were developed with the aid of physicists, and earlier developments in biological warfare were made possible with the assistance of chemists. Whether or not social scientists are as complicit as Foucault suggests, there is evidence that social scientists are more responsive to national needs than researchers in the natural sciences and are more inclined to publish for a national audience rather than an international audience. Like scholars in the humanities, social scientists "publish more often in their mother tongue and in journals with a more limited distribution" (Lavirière et al., 2006: p. 521). Thus, the research of social scientists is more often created for local consumption and is more often directed by local concerns than research in the natural sciences.

Methodologies

Epistemic communities are not immune to influence from the broader culture in which they work. For example, there is a long tradition in German-speaking countries of regarding the social sciences and the natural sciences as fundamentally different, distinguished by their different methodologies. The social sciences, unlike the natural sciences, are alleged to be interpretative enterprises and to employ hermeneutical methods, like the methods used in the humanities. Hermeneutical methods are concerned with getting at the meaning of human actions and institutions. A hand gesture can mean different things in different cultures. A particular gesture that might cause hostility in one culture may convey friendship in another culture. Max Weber, for example, holds this view (see Weber, 1977). In contrast, in the English-speaking world, researchers in the social sciences frequently aspire to emulate researchers in the natural sciences, employing similar methods, and having similar aims. In fact, this attitude is not unique to social scientists working in English-speaking countries. In his research on suicide, Durkheim looks for patterns in the statistical data across a range of European countries, much as many natural scientists look for patterns in the data they collect (see Durkheim, 1951).

Defining Disciplines

The situation is even more complex than this picture suggests. A single science can have different developmental trajectories in different cultures. Anthropology, for example, has developed in significantly different ways in the United States and the United Kingdom, largely a consequence of differences in the institutional organization of the various sciences in the two cultures. In the United States, anthropology is clearly identified with the social sciences, and archaeology is regarded as one of the four major subfields in anthropology. In contrast, in Europe, archaeology is more closely connected with the discipline of history (see Sharer and Ashmore, 2003: pp. 33, 60). Similarly, although the field of criminology is identified as part of sociology in the United States, in Europe it has affinities with the fields of medicine, psychiatry, and law (see Akers, 1992: p. 5).

Broader social factors also sometimes influence the development of a field in specific national settings. For example, in the United States, the field of criminology became less academic and more concerned with vocational training after "the 1967 President's Commission on Law Enforcement and the Administration of Justice" (Akers, 1992: p. 7). The Commission recommended "enhancing higher education for criminal justice personnel," which led to a great expansion of undergraduate programs in criminology (p. 7). Similar stories could be told about other disciplines (see Patterson, 2001: p. 4, for a discussion of how anthropologists in the United States came to study acculturation and assimilation as immigration was increasing).

Summary

Research on epistemic communities and collaboration in the social sciences has deepened the understanding of the challenges social scientists face when they investigate the social world. But there is not a widely accepted unified theory of how social scientists realize their epistemic goals. This is in part a function of the fact that different disciplines, fields, and subfields have different norms and practices, and thus generate and verify knowledge through different means. As collaboration becomes more common in the social sciences, it is likely that social scientists will continue to investigate the benefits and drawbacks of working collaboratively. Although

the pooling of resources afforded by collaboration enables social scientists to investigate things they might not otherwise be able to investigate, new challenges arise as social scientists need to develop the social skills to work in collaborative research settings.

Abstract

Epistemic cultures are cultures of creating and warranting knowledge; 'epistemic' refers to knowledge and truth-related goals and practices as central elements of scientific and professional fields. The notion epistemic culture challenges the idea of the epistemic unity of the sciences and suggests that the sciences are in fact differentiated into cultures of knowledge, which are characteristics of scientific fields or research areas, each reflecting a diverse array of practices and preferences coexisting under the blanket notion of science. This article traces the history of the concept, its various meanings, original research that supports the idea, and recent extensions to areas of practical relevance (such as learning and policy making), to the humanities, finance, and other fields. It shows how the notion has been used to explain the difficulties of interdisciplinary research. The article also discusses the uses of the idea of 'knowledge cultures' on a macrolevel to compare and assess attitudes toward nonknowledge and epistemic mentalities inherent in the knowledge-related institutions and policies of particular countries.

What Are Epistemic Cultures?

The term *epistemic cultures* grows out of the so-called laboratory studies of science and technology, a direction of research that focuses on the practice of science as distinct from the history of scientific ideas, the logic of scientific discovery, or the analysis of scientists' writings. The process of doing science tends to become black boxed once its outcomes are accepted as 'facts' or as technologies in use. In the early 1970s, lab studies emerged as a strategy to open up this process by watching scientists at work. The early laboratory studies attempted to work out how scientists accomplish and create their findings by focusing on a particular lab and field and by choosing an observational methodology (Knorr Cetina, 1981; Latour and Woolgar, 1979; Lynch, 1985). Some also focused on questions of organization and learning (Traweek, 1988). Second-generation studies targeting scientific practice often had broader goals and more diverse methodologies. The term epistemic cultures entered the vocabulary via Knorr Cetina's comparative study of two influential scientific fields, high-energy physics (HEP) and molecular biology (1991, 1999). The question that motivated a comparative approach was could the findings of early laboratory studies be generalized across scientific fields? Could one extrapolate from the kind of work conducted in the benchwork labs that had originally been studied, to other sciences: for instance, those that involved both huge detectors and equally huge collaborations? The notion 'epistemic cultures' is in a sense the answer to this question. It disrupts the idea of the epistemic unity of the sciences and suggests that the sciences are in fact differentiated into cultures of knowledge that are characteristic of scientific fields or research areas, each reflecting a diverse array of practices and preferences coexisting under the blanket notion of science.

Knorr Cetina defined epistemic cultures as cultures of creating and warranting knowledge (1999: p. 1); and as amalgams of arrangements of mechanisms and elements bound together by affinity, necessity, and historical coincidence which, in a given field, make up how we know what we know. The word 'epistemic' is significant here. It points to knowledge and truth-related goals and practices as the central elements of scientific fields. When we study the epistemic side of science we do not focus on laboratories as organizational units, on scientists as workers, or on scientific disciplines as professions – we focus on how what counts as knowledge and technology is accomplished in designated settings through specific strategies that generate, validate, and communicate scientific accomplishments. When you study epistemic cultures you are more likely to investigate how practitioners distinguish signal from noise, or move from *in vitro* experimentation to *in silico* simulation, or how they decide which figure to trust when experimental outcomes are uncertain, than on these practitioners' budgets, career moves, or conflicts with management. In a sense, you step through the looking glass – everything is the same, budgets, careers, and managers still matter, yet everything is different. The setting is now a new world defined by research in which much of what we focus on when we study organizations and professions gets bracketed and pushed into the background, and priorities shift to needs and problems that arise with objects and equipment in laboratory life. Experimental high-energy physicists somewhat dismissingly distinguish between 'the system' and 'the science' or 'the experiment.' The system was the world of administration and financing which made what they did possible, but that was sharply differentiated from what they were possessed by and cared for, namely the science. Practitioners themselves draw a line between the epistemic and the nonresearch side of science, which they often try to avoid and keep at bay. We follow practitioners when we study epistemic cultures – but, as they do, we also need to understand and watch 'the system,' and how it enables and constrains the science.

The notion 'epistemic' targets a particular level of analysis. But what does the notion of 'culture' target? A first answer is that it targets a level of practice, rather than the level of symbols and meanings, which students of culture usually tend to examine. Practices are not devoid of meaning; to discover practices, it is necessary to gain familiarity with the frames of meaning within which people enact their lives, and symbolic

rituals or writings are equally practices. But to capture how scientists create knowledge, one also needs a working familiarity with what they do in laboratories – the spaces where most of the activities of the natural sciences take place – and with the way meaning is nested in and arises from use. For example high-energy physicists approached their detector, a massive machine, via metaphors of a living being. This was not *dissociated* from inquiry, but formulated their ways of experiencing the machine *during* inquiry. The focus on practice moves the level of cultural analysis 'down' to the realm of material regularities, but without losing sight of symbolic regularities and the ways these are associated with the material.

Material regularities, of course, include more than human practice, and this gets us to a second answer to the question of 'culture.' The comparison between different sciences brought to the fore distinctive characteristics of each field which included a wide range of elements; for example, distinctive traditions of teamwork and publication, specific epistemic strategies, different meanings of the empirical, and distinctive notions of reality as it was dealt with by the science. Different fields appeared to employ not only different vocabularies of knowledge and target different objects of study, but they saw different things: reality was an interiorized system of reference and not shared across disciplines. Science was not as unitary as had been thought; not just in relation to method (the Vienna Circle of philosophers has proposed the methodological unity of science) but also with respect to how reality itself was accessed and constructed. Economists, for example, think of the economy in terms of 'fundamentals,' which on a macroeconomic level are factors like interest rates, GDP growth, the trade balance and deficit, inflation levels, and so on. These factors indicate an underlying reality – the state and health of an economy – which macroeconomists tend not to pursue further. Real-time economic transactions and their meanings for people – in other words, everyday reality – is not the baseline from which such fields start. Rather one starts with 'measures,' variables with causal powers which describe the being of an economy. Different epistemic cultures locate such fundamental descriptors differently, although they remain aware of the basic structures and elements we distinguish in everyday life.

What the notion of epistemic culture implies therefore is that the disunity of science potentially extends to all levels, including the ontological. In fact, it is hard to see how it could be otherwise. Cultural specificities arise, one assumes, when domains of social life become separated from one another – when they curl up upon themselves and become self-referential systems that orient more to internal and previous system states than to the outside environment. The cultural scripts that emerge may be 'policed' by participants who may see to it that activities are plausible, effective, displayable as rational; scripts may also grow together in the sense of becoming mutually adapted over time, forced by the need to accomplish things in practice. All this may make cultural domains at least somewhat internally coherent (though certainly not free of conflict) – in addition to being separated and bounded. The ATLAS detector in HEP, consisting of layers of 'barrel' and 'endcap' instruments and a beampipe, requires that all its parts work together without detrimental interference – no cooperation, no results! Science and expertise are obvious candidates for cultural divisions; they are pursued by specialists separated off from other specialists by long training periods, intense divisions of labor, distinctive technological tools, particular financing sources, and the need to come up with results and display them in public through publishing.

The notion of an epistemic culture takes up where this assessment leaves off. It brings into focus the content of knowledge-oriented lifeworlds as lived, taken for granted worlds, including specific constructions of the referent (the objects of knowledge), distinctive models of the epistemic subject (scientists), and particular structures of existence with which a field engages. It is particular to these lifeworlds that they include 'strange' (e.g., nonhuman) entities with which some form of coordination has to be achieved. The notion of a scientific laboratory as distinct from the related idea of an organization may illustrate this. Laboratories are organized. But unlike the notion of 'complex organization' they are not about the coordination of human groups. Where knowledge is concerned, the notion of organization tends to assume away the rich processes and relationships between experts, organizational formats, and epistemic objects, through the simple presupposition of knowledge workers' technical competence. While the ways in which object-centeredness is enacted in organized laboratory settings is open-ended, the term itself points to 'mixed' systems of care and attention developing around epistemic entities in which organizational governance crucially works through the manipulation of problem content, rather than solely through people and structures.

The second answer to the question of what the notion of an epistemic *culture* targets, therefore, is that it brings into view not only the level of practice, but also a nexus of lifeworlds and the machineries of knowing that develop within a specialty. Epistemic cultures tend to have rich and potentially complex internal environments, with warped geometries that result from their turning or curving in upon themselves and a tendency to impose and expand their own structures and concerns. But they can be torn by conflicts and disagreements and the less than peaceful coexistence of participants (human and nonhuman). Machineries of knowing may or may not include a tactics of conflict prevention and management. To make a collaboration of several thousand physicists (and numerous detector parts) work for the 20–30 years *longue durée* of a HEP experiment, numerous tactics that enhance cooperation were developed. Such tactics may be lacking in fields where individual scientists pair up with individual topics of research. In the second case, we are likely to find mechanisms in place that discourage cooperation and justify its opposite.

Three Illustrations for Epistemic Cultures – HEP vs Microbiology

To illustrate how different epistemic cultures shape the production of knowledge, consider some distinctions between HEP and microbiology. First, the two fields produce two kinds of knowledge. HEP processes and deals with ephemeral,

'phantasmatic' objects – subatomic particles – which are too small and too fast to be observed directly. What HEP 'sees' are the traces these particles create in detectors. HEP thus depends on massive arrangements of technical instruments (detectors and accelerators), which are placed seven stories underground. Since these instruments are built afresh for every new experiment, creating, calibrating, protecting, and understanding this equipment takes up much of the time of an experiment. Knorr Cetina shows that the results emerging from such experiments involve, and may almost entirely consist of, "negative knowledge" that is not "non-knowledge but knowledge of the limits of knowing, of the mistakes we make in trying to know, of the things that interfere with our knowing, of what we are not interested in and do not really want to know" (1999: p. 64). Microbiology, in contrast, deals with natural and quasi-natural objects, accesses and manipulates them directly, and despite the existence of large genomic centers, still mostly involves benchwork in small labs. Physics collaborations today involve approximately 2000 physicists, while benchwork groups may range in size between a few and three or four dozen scientists. Microbiology seeks positive knowledge rather than negative knowledge, often accomplishing it through the 'blind variation' of experimental conditions (1999: p. 108).

This study also compared symbolic classifications in the two fields. Although physicists have an elaborate technical terminology at their disposal, they frequently discussed machine and particle behavior in terms of a symbolic vocabulary, using metaphors that described the detector as if it had a physiology and was a living being. For example, detectors could age and have various ailments and illnesses. Detectors also seemed to be moral and social beings. They could act up and behave 'well' or 'badly,' and various detector parts could communicate with each other and 'agree' or 'disagree.' They could 'cooperate' or not (Knorr Cetina, 1999: pp. 118–119). Machines then were categorized in terms of a vocabulary of organisms. Molecular biology, on the other hand, which dealt with organisms and organism's parts, resorted to technical images. A single cell organism or a laboratory mouse was seen as a production system that could be standardized, controlled, optimized, and reproduced.

The two fields also exhibited markedly different forms of social organization, and understandings of how laboratories and experiments should be managed. HEP required large collaborations that worked together as 'posttraditional communities.' They used collective and communitarian principles that configured the collaboration, rather than the individual, as the epistemic subject (Knorr Cetina, 1999: pp. 166–171). The simplest illustration of this – and one of the mechanisms for accomplishing a collective order that rejected hierarchy – was that hundreds of authors, essentially all accredited members of the collaboration, were listed alphabetically on publications. In other words, epistemic agency was delegated to the experiment as a whole; for example, conference invitations were extended to the experiment rather than to individual scientists. Delegating epistemic agency to the collective unleashed something that was urgently needed in this area: cooperation. In contrast, microbiological laboratories were organized around a laboratory leader, the most powerful individual in a hierarchical structure with a fixed position (the last) on publications. In contrast to HEP, cooperation was always tenuous within the individualistic and hierarchical structures of molecular biology labs; it required trust and continual renegotiation of interest (Knorr Cetina, 1999: p. 171).

Preceding Notions of Knowledge, Culture, and the Disunity of Sciences

Several early analysts, writing from the viewpoint of philosophy or sociology of knowledge, developed ideas about the situatedness of thinking and knowledge production within a particular society or community. These authors also often suggested that truth might not be as universal as it seemed, but is relative to what shapes a particular style of thinking. These arguments put into question the notion of linear progress in science. For example, Ludwik Fleck (1979), a biologist and doctor writing in the 1930s, developed the notion of a thought collective and of thought styles. Fleck proposed that scientists were in fact locked into a particular style of thinking that dominated in a thought collective: a scientific specialty that developed its own language and cognitions which were not understandable by other thought collectives. Fleck has often been credited with anticipating and preceding Kuhn's (1962) notion of the incommensurability of scientific paradigms, and the idea that scientific revolutions rather than linear progress describe and explain change in science. Mannheim (1990), writing in the 1950s as a sociologist, was interested in how social conditions shape scientific thinking. He emphasized the 'Seinsgebundenheit' of knowledge, using a notion that anticipates feminist notions of knowledge as gendered and inescapably perspectival (e.g., Hartsock, 1998).

Cultural differences between disciplinary cultures were also noted and elaborated. Snow (1959) famously argued that there is a cultural gap between the humanities and the natural sciences; and Lepenies (1985) saw the social sciences as wedged between these two groups of disciplines. Kuhn's notion of a scientific paradigm – what a scientific community shared in terms of methodological preferences, theory, and experimental practice – paved the way for a cultural approach that was less general than Snow's and more grounded in the empirical details of the internal processes of science. Snow's notion of the two cultures gained currency again through the so-called Science Wars in the 1990s, when combatants from the natural sciences and from sociology of science debated the question of relativism and what it meant to say that knowledge was constructed. In an attempt to bridge the divide that had ensued, Collins and Labinger (2001) brought together social and natural scientists, and found broad agreement between them in their dialogue about the legitimacy and authority of science.

Snow's ideas revived themes that were part of the Methodenstreit (struggle over methods) in German universities in the 1890s, and that were echoed again later when Habermas (1971) distinguished between instrumental and communicative knowledge during the debates over positivism in England and Germany. He linked the differences to human interests rather than culture.

The notion of epistemic culture contrasts with these debates in several ways. First, it is an empirically based concept, approach, and theory that requires close attention to knowledge production at the site of its respective practices. Second, it is not pitched at the level of whole disciplines but at the level of research fields, and it does not sit well with general dichotomies that group sets of disciplines together based on how they are named rather than what they do. It is entirely possible, from an epistemic culture point of view, that the differences between some disciplines are not as substantial as the differences between *subfields* of a single discipline; or that a natural science field appears closer to a humanities area than to another physics specialty. HEP can again serve as an example. Given that it works with traces of particles that are always historical (in the sense that they have always already decayed when they are 'seen' and processed), and since the movements of these particles have to be elaborately 'reconstructed' (native term), HEP appears to have more in common with semiotics than with a benchwork science. Although it does not use the same methods of reconstruction, results are often painfully indirect – in the sense of requiring multiple interpretations and many intermediary steps, deriving results from traces for which there is no original. When one studies experimental HEP it helps to have knowledge of historical processes, of semiotics, and of closed system theory. The same cannot be said about the type of molecular biology that is based on scientists' embodied work, requiring scientists to develop 'golden hands' (to become skilled experimenters) and a 'feeling for the organism' they handle (Fox Keller, 1983).

The Career of the Concept of Epistemic Cultures

The notion of epistemic cultures was widely received in social studies of science and in the sociology of scientific knowledge, as well as in social theory and in other fields (e.g., Burri, 2005; Cazaux, 2003; Cutcliffe, 2001; Markovsky, 2000; Mogey, 2001; Pinch, 2000). It motivated further studies that we group together as follows. First, authors used the notion to investigate in detail the epistemic characteristics of further specialties and fields of knowledge inside and outside academia. Second, several authors elaborated the notion of epistemic cultures and developed it further. Third, the notion was used to explain the difficulties of interdisciplinary research. Fourth, research on organizations used the concept to understand and optimize complex organizations. Fifth, there is a heterogeneous category of studies that investigates features of knowledge areas that can be understood in terms of the notion of epistemic cultures.

Analyses of Research Fields Using the Notion of Epistemic Cultures

Several authors enriched the notion of epistemic cultures by analyzing a variety of scientific disciplines, and by characterizing the respective fields and their truth-related strategies and practices. Some authors also applied the notion to nonscientific contexts, such as in online platforms and politics. For example, Yonay and Breslau (2006) studied the epistemic culture of 'mainstream economics' (p. 349), asking how economists connect their formal models, which are based on unrealistic assumptions, with empirical research and data-driven inquiry. They argue that their epistemic culture enables them to mediate between the two sides. "Rather than involving scientific instruments or data-gathering procedures, this mediation is accomplished by vaguely defined but generally accepted conventions regarding the movement from reality to models" (p. 377). The models construct an easy to handle and manipulate version of reality, an epistemic strategy familiar to both social sciences and natural sciences.

Along similar lines, Müller (1996) applied the concept of epistemic cultures to the social sciences and their 'modeling dilemma,' using it to formulate differences between practices of generating and validating knowledge. Reuter (2013) also applied the idea to the social sciences, calling for more reflexive intercultural research that makes practitioners aware of their own epistemic strategies because they may become problematic when other cultures are investigated. Grégoire Mallard, in an article based on ethnographic research with Balzac scholars (2005), highlights the presence of diverse epistemic cultures in literary criticism, a humanities field, by tracing the evolution of Editions of Balzac's *La Comédie Humaine*, from a unified unadorned text in the 1930s to a searchable electronic format of different versions. He shows how the different schools of interpretation in Balzac criticism (traditional, semioticians, sociocritics) constructed these diverse editing technologies to influence the evolution of literary theories. Kuoppamäki (2002) analyzed architectural models resulting from particular sketching techniques, which are part of a common 'configurational epistemic culture.' Architectural models or sketches cannot be true or false and it would not be appropriate to use these categories in this case. Accordingly, we are not seeing a 'truth machinery' at work, as in a natural science, but configurational strategies: the epistemic culture connects the architectural knowledge of many with the configurational sketch of the individual. Cole (2013) investigated the epistemic culture of forensic sciences calling it 'forensic culture,' and cultural patterns were also identified in mathematics. In her study about strategies of proofing and validating mathematical results, Heintz (2000a,b) shows that mathematics experiences epistemic cultural variations over time. But mathematics also illustrates the difficulties of sociological inquiries, given its low degree of interpretative flexibility and the high degree of consensus about the validity of epistemic strategies.

Epistemic Cultures in Nonacademic Contexts

As Epstein (2008) argued, the concepts and ideas of science and technology studies potentially migrate to other sociological fields and they may become useful to the study of nonacademic areas, particularly in a knowledge society in which knowledge processes become differentiated and permeate most areas of practice. Epistemic cultures will therefore be found in expert settings outside of the scientific laboratory. For example, Wagner and Newell (2004) explain the diverse uses of standardized software packages in universities in terms of the differences between the epistemic culture of the lower ranked members of the administration, the higher university management (the level of the university president or rector and the vice-chancellor), and the level of researchers.

Jensen (2007) used the idea of epistemic cultures to challenge traditional theories of learning. Assuming that epistemic cultures 'spill over' from academia to professionals, she seeks to identify professional cultures in terms of how they engage in continuous learning. Jensen compared nurses, accountants, teachers, and computer engineers. All groups use the rhetoric of the knowledge society, saying that they are lifelong learners. But how they access new knowledge varies considerably between these groups. The learning process is an 'unfolding process' characterized by a 'back and forth' trial and error – and by the interference of emotions, such as boredom or frustration. Jensen shows that epistemic cultural characteristics do not spill into nonacademic professions automatically, and recommends that the process should be supported by learning aids and tools that are adapted to professional cultures.

The policy-making area has also been studied with respect to its knowledge characteristics. In her study of a political campaign, Heath (2012) investigates the relationship between the dominating epistemic culture of experts and the public policy that ensues, finding that when knowledge production strategies change, public policy also changes. Heath examined the impact of quantitative studies that correlated "the growth of welfare, the rise in unwed childbearing, and the poverty" of individuals (p. 385), and claimed that children born from unwed couples are more likely to end in poverty. These findings informed public debates and lead to regulation promoting marriage. Heath argues that "the political efforts at establishing an epistemic culture of marriage promotion in Oklahoma built on a general 'knowledge culture' concerned with the significance of heterosexual marriage for sustaining the social fabric of American society" (p. 392).

One of the most knowledge-intensive areas is the area of finance, home to various lines of traditional financial research but also to the evaluative epistemic cultures of rating agencies (e.g., McKenzie, 2011), to information knowledge processes characterized by an epistemic of consumption (Knorr Cetina, 2010), and to technologies that raise their own questions of culture-formation and transformation (Knorr Cetina and Preda, 2007). A final example for a nonacademic epistemic culture is the widely known online encyclopedia Wikipedia. Wray (2009) critically compares the norms, collaboration-styles, and knowledge validating practices of Wikipedia authors with those of scientists, arguing that Wikipedia encourages a 'puckish' culture, in contrast to science where seriousness dominates. Wikipedia includes (more or less harmful) jokes, defamations, and anonymous contributions written to undermine its mission (e.g., fake biographies of celebrities) – hence the notion 'puckish' – while there is little place for humor and jokes in science.

Further Developments of the Notion Epistemic Culture

The last sections focused on how authors in various scientific, professional, and expert contexts have used the notion of epistemic culture. This section offers three examples of studies that expand the notion theoretically and develop it further. For example, Böschen et al. (2006) argue that there are not only different cultures of producing and validating positive knowledge but also 'cultures of nonknowledge.' These manifest different degrees of awareness of and attention to nonknowledge; and different ways of anticipating the unexpected, of associating it with risk, and of dealing with unforeseen and unintended results. Some fields such as ecology cherish a naturalistic view of the world in order to avoid the unintentional elimination of unrecognized key details of a phenomenon. Giere (2002) criticizes Knorr Cetina's "most provocative idea" (p. 639) of the elimination of the epistemic subject (see Knorr Cetina, 1999: pp. 159–191) in experimental HEP. He argues that this part of the epistemic culture of HEP could also be understood in terms of notions of distributed cognition: of expertise distributed among the hundreds of members of a HEP experiment and physics instruments. The more individualistic sciences would then simply lack this feature.

Finally, Lamont provides a nuanced account of 'epistemological styles' (Lamont, 2009: p. 54) prevalent in different social sciences and leading to different criteria of evaluation when practitioners evaluate grant proposals, that reflect different disciplinary cultures. Lamont distinguishes four styles of identifying and defining excellence in proposal evaluations, which she links to differences in their consensus orientation: comprehensive, constructivist, positivistic, and utilitarian. In her account, philosophy is a 'problematic' discipline whose weakness and strength is its preference for discussion and argument rather than quick decisions. English literature, in contrast is a demographically threatened low consensus discipline with intellectual disagreements at its core. History, like economics, is much more consensual. It defines excellence on the basis of good 'craftsmanship' in archival work. Both history and economics appear to have no problems in defining and recognizing excellence (p. 103).

Epistemic Cultures and Questions of Interdisciplinary

One major area of research in which the notion of epistemic cultures has served as a descriptive and explanatory concept is that of interdisciplinary or multidisciplinary research. What happens when different epistemic cultures get in touch with each other? How do members of different epistemic cultures cooperate with each other, and do they even understand each other? Conversely speaking, does the existence of epistemic cultures explain and predict some of the difficulties of interdisciplinary research? While the concept of epistemic cultures "is useful for highlighting the specificities of the different scientific cultures and research practices […]", Albert et al. argued (2008: p. 2522) that "it remains somehow static as it does not provide insight on the power relationships between groups of scientists." Differing epistemic cultures are likely to devalue other epistemic cultures, especially when they do not have direct contact with them (2008).

In line with this argument, the notion of epistemic cultures has been used to highlight and explain conflicts between fields, which may be due to incompatible practices of knowledge production. Mørk et al. (2008) suggested that such conflicts can limit the productivity of knowledge creation and make it more path dependent. This means that once knowledge production takes off in a particular direction, it is difficult to roll it back to the beginning and start over in a different direction. Van House (2004) studied a digital platform that

provides environmental data for members of different epistemic cultures, including scientists, laymen, and bureaucratic organizations. She finds that the online communication makes the differences between epistemic machineries visible, but it also "facilitates the flow of information […] among epistemic cultures" (Van House, 2004: p. 11).

Other authors do not focus on conflicts between epistemic cultures but analyze the change and development that occurs when members of epistemic cultures meet and have to confront their differences. Kastenhofer (2007), for example, shows how biotechnology emerged from a process of convergence between several fields with quite different epistemic cultures. Kastenhofer argues that such processes of convergence can encourage cooperation between disciplines, integrate research groups and organizations, and assimilate epistemic cultures. Jacobs (2013: Chapters 1 and 4) argues more broadly that interdisciplinary research, when it occurs, leads over time to new syntheses that create new specialties with their own research strategies, journals, and institutional strongholds. In other words, they develop their own specialized epistemic culture. Other studies find that processes of 'convergence' may also produce uncertainties and inconsistent knowledge claims. For example, Torgersen (2009) argues that biology became 'interdisciplinary' with the development of genomics (see also Dean, 1979), and had to rethink criteria of evidence, experimental practices, object-classifications, and the role of hypotheses in research. He also argues that, in the end, a new epistemic culture emerged, but not without a lengthy process of specifying and reconfiguring previous cultural practices. Kertcher (2010), studying electronically mediated collaborations, identifies problems of innovation adoption having to do with differences between epistemic cultures participating in the collaborations, but he also shows ways through which participants managed to build bridges between disciplines while attempting to achieve interdisciplinary knowledge integration.

Interventionist Studies: Epistemic Cultures in Organizations

Another body of literature deploys the notion epistemic culture to intervene in, manage, or change social domains. The studies typically focus on knowledge-intensive organizations, arguing that the notion can serve as a tool in organizational design and professional development. Management theories pay attention to epistemic cultures because the notion helped to develop their "sense of the glue that keeps tightly knit groups of researchers together as 'epistemic communities' or communities that are defined by their shared tacit knowledge of process, context, history, and culture […]." The central management question here is: "How open are these coherent groups to cooperation and partnership with others?" (Gore, 2011: p. 99). The literature suggests that different epistemic cultures – defined as sets of shared knowledge-oriented practices – characterize not only scientific research, but also organizations and strategy (Kaplan, 2011: p. 320), and it recommends a practice-oriented approach to understand these cultures (e.g., Clegg et al., 2011: p. 117).

Dragonetti (2003) argues that management theory accepts knowledge to be an important resource for corporations. Still, it does not ask how knowledge is produced within corporate contexts. Based on an ethnographic study of several companies, she shows that the process of knowledge creation in organizations departs from the linear models on which knowledge management relies. Such models are like straightforward recipes, when in fact the real processes of knowledge creation appear much more chaotic and ambiguous. Dragonetti distinguished two types of knowledge: traditional knowledge ('know-how') and declarative knowledge ('know-what'). 'Know-what' was less codified and included social routines; while 'know-how' circumscribed all work-related routines and was strongly codified. Know-what and know-how involved different knowledge creation processes. For example, when know-how was created the pressure to achieve consensus was high, resulting in a more hierarchical social organization. Dragonetti calls upon management models to come up with an empirically based 'knowledge theory' to better control knowledge production within corporations.

Gore (2011) provides another example of the use of the epistemic culture notion in organizational research. He studied how universities' knowledge management can encourage cooperation between groups that share an epistemic culture (e.g., academic researchers) with relevant groups in industry. Following Gore, the notion epistemic culture is not only an analytic concept that explains differences between groups of researchers, but also a starting point for developing strategies that overcome these differences and prompt people to cooperate. Moisander and Stenfors (2009) make similar suggestions. In their empirical study they discuss the challenges of different epistemic cultures, different kinds of knowledge, and conflicting conceptions of the subject matter of knowledge (p. 229). The conflicts divide management science scholars and practitioners who may be required to use the strategic tools developed by research. Managers in 'postbureaucratic organizations' exhibit different epistemic cultures than 'modernist' operation research and management science scholars (p. 234). For Weissenberger-Eibl and Ebert (2010) epistemic cultures are an organizational characteristic that captures how knowledge is treated within the organization. Since management should consider all accepted ways of using, identifying, storing, distributing, and validating knowledge, organizational epistemic cultures are a central aspect of the management of organizations. Another study analyzes how PowerPoint presentations are engaged in strategy making in corporations and organizations (Kaplan, 2011). She argues that PowerPoint is not just effective or ineffective; it should rather be seen as part of 'strategy-in-the-making' (Moisander and Stenfors, 2009), and as such it shapes organizational knowledge.

Macroepistemic Cultures/Knowledge Cultures

The concept of epistemic cultures can also be used on a macrolevel to characterize the knowledge attitudes, institutional arrangements, and knowledge policies of different societies. Knorr Cetina (2007) proposed the notions of knowledge cultures and macroepistemic cultures for this reason, to

differentiate this type of analysis from that of the truth-related strategies and categories which are central to understanding research cultures. We tend to see knowledge as a component of society: of its economic, social, and political life. But we can also turn the argument around and consider social, political, and economic life as part and parcel of a particular knowledge culture. The distinction is not simply between the knowledge processes and their cultural context. It is rather a distinction between the interiorized description and conceptualization of knowledge processes opened up through empirical inquiry (the epistemic cultures) *and the description of society in knowledge terms*. For example, national legal frameworks and research expenditures not only enable, restrict, and contextualize research, they also exemplify the knowledge culture of a country.

Jasanoff (2005) provides an example for different macro-level knowledge cultures. Jasanoff (2005: p. 151) studied questions of assisted reproduction, stem cells, genetically modified food, and the status of an embryo (whether a 'lump of cells' is a person, or a fetus, or just a lump of cells) by investigating the national interpretations of the US, Great Britain, and Germany. As governments and the public interpret through debate and regulation what biotechnology promises or threatens, they come to quite different conclusions depending on whether the procedure is perceived to result in boundary crossing 'monsters,' is linked to a disorder, or is simply seen as giving rise to new hybrid forms. The resulting legal frameworks (Germany forbids gestational surrogate mothers, for instance) reflect attitudes toward new knowledge with wide ranging institutional, financial, and epistemic consequences, for example for the type of research viable in a country.

Another example of a knowledge-related category pertaining to the wider society is the notion of a risk society: the idea that we are increasingly confronted with risks and uncertainties emanating from the very technological, scientific, and other achievements of modernity. The risks are seen as ontologically threatening and cannot simply be eliminated by more expert knowledge (e.g., Beck, 1992). From the present perspective, the description of Western societies as risk societies expresses and elaborates a particular cultural viewpoint on risks: an 'epistementality' that may shape the way expert knowledge is embedded in legal frameworks, schemes of citizen-participation, and the like (Gibbons et al., 1994).

Epistemic Doubt During Adolescence

Robert B Ricco, California State University, San Bernardino, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Naïve beliefs about the nature of knowledge and knowing – epistemic beliefs – are present from childhood onward and undergo development through a relatively fixed sequence of levels from realism through relativism to rationalism. There appears to be more than one pass through this sequence, with the first pass occurring from middle childhood through late adolescence, and the second pass occurring from late adolescence through early adulthood. The period of relativism during adolescence is characterized by generic doubt about the possibility of establishing a valid, rational basis for one's beliefs, coupled with interesting and varied ways of coping with that doubt.

Epistemology is a subdiscipline of philosophy that is concerned with the nature, origin, limits, and validation of human knowledge (Hofer, 2002). Several decades of research within the fields of psychology and education have made it clear that lay adults, adolescents, and older children possess an interrelated set of beliefs about knowing and knowledge, which might be called a naïve or informal theory of epistemology (Hofer, 2004; Kitchener, 2002). Further, there is substantial agreement that given certain social and educational experiences, these naïve epistemologies undergo development in accordance with a relatively fixed sequence of levels. Several developmental models have been proposed (e.g., Baxter-Magolda, 1992; Chandler et al., 2002; King and Kitchener, 1994; Kuhn et al., 2000b; Perry, 1970). There is strong agreement across these models concerning the beginning and end points of development and considerable agreement about a key intermediary level. At the same time, the models differ substantially with respect to timing and the proposed age of onset for the various levels.

The first models of the development of naïve epistemologies focused on late adolescence through early adulthood and were derived from cross-sectional and longitudinal data regarding change in epistemic beliefs across the college years and beyond. Perry (1970), King and Kitchener (1994), and Baxter-Magolda (2002) generated similar models covering this age period. The models implied that there was little significant development concerning epistemic beliefs prior to the later stages of high school. In the initial level or stage of these models, variously described as an absolutist (Baxter-Magolda, 2002; Kuhn, 2000), prereflective (King and Kitchener, 2002), realist (Chandler, 1987), or dualist (Perry, 1970) level, knowledge is considered to be a direct copy of objects and events in the world. Fully objective and devoid of subjective elements, knowledge, in this view, derives from experts and other authority figures or from direct personal experience. Facts originating in this manner are self-evident, beyond dispute, absolutely correct, and certain. Within this position, there is no obvious need for justification or validation of knowledge claims above and beyond a simple, and allegedly transparent, process of assembling the facts and determining which position in a dispute is supported by them. If the uncertainty of knowledge claims or the indeterminacy of problems and controversies are at all acknowledged within this initial epistemic level, it is merely in a temporal sense. That is, observations can be in error, either because of faulty instrumentation or methodology, or because the observer has only limited access to the facts, but further research – individual or collective – will eventually resolve disputes in all such cases.

The epistemic realism of the first stage of development is progressively undermined by the gradual appreciation of the subjective, interpretive, and perspectival nature of all knowing, with the resultant understanding that certainty and determinacy are not generally attainable except within contrived or limited conditions. Knowing is increasingly viewed as influenced by prior knowledge, interests, goals, expectations, and other biases. Meaning is understood to be a construction by the knower in interaction with the known. Ultimately, within each developmental model, these insights into the constructive nature of the knowing process lead to the emergence of a full-blown or radical relativism that reflects a complete swing from the pure objectivism of the first developmental level to a pure subjectivism wherein there are no nonarbitrary beliefs. Within this multiplist (Kuhn et al., 2000b) or relativist (Chandler et al., 1990; Perry, 1970) level of epistemic development, there is essentially no distinction between fact and opinion, and all bases for determining what is true or right are considered arbitrary. Some researchers have gone so far as to claim that relativism constitutes a fifth, and distinctly adult, stage of Piagetian cognitive development – a postformal stage that supplants the logic of formal operations with a dialectical logic (Kramer et al., 1992).

Finally, at least in some individuals, relativism gives way to an evaluativist, rationalist level (Chandler et al., 2002; Kuhn et al., 2000b) – the end point of development – also described as commitment within relativism (Perry, 1970), reflective reasoning (King and Kitchener, 1994), or contextual knowing (Baxter-Magolda, 2002). In effect, the extreme tendencies toward objectivism and subjectivism, evident, respectively, in the two previous developmental periods, are now coordinated and balanced. The key advance is an appreciation that there are fallible but legitimate criteria for adjudicating between competing claims and that choice in the face of uncertainty and indeterminacy can still be rational. As in the relativist period, beliefs are understood to have a subjective and defeasible aspect and neither side in a controversy is considered to be right in any simple or

absolute sense. However, it is now recognized that one side may be legitimately superior to the other and that this is demonstrable through a kind of reasoning to the best explanation based on rational considerations of the available evidence.

Epistemic Doubt and Adolescent Development

Research guided by this developmental model initially led to conclusions that reflection upon, and revision of, naïve epistemic beliefs was more characteristic of early adult development than of the adolescent or preadolescent years (Kitchener, 2002). More recent findings, however, indicate that there is more than one pass through this sequence of levels and that epistemic development may be recursive (Chandler, 1987), with the same issues regarding the nature of knowing being addressed at multiple points in development as the individual encounters distinctly new academic or social contexts (Chandler et al., 2002). There may also be periods of regression to earlier positions. While data with college students does point to a relatively late-occurring progression through these developmental levels, it is equally clear that when measured in age-appropriate ways, the same progression is present somewhat earlier (Hallett et al., 2002). There is now ample evidence, during preadolescence, or even middle childhood, of relativistic thinking (Boyes and Chandler, 1992; Kuhn et al., 2000b; Mansfield and Clinchy, 2002), and an appreciation of the active role of the knower in the acquisition of knowledge (Carpendale and Chandler, 1996; Pillow and Henrichon, 1996; Reich et al., 1994; Smith et al., 2000). As Chandler (1987) has pointed out, adolescence is, very typically, a period of profound *epistemic doubt*, i.e., doubt about the possibility of establishing a valid basis for one's beliefs, coupled with interesting and varied ways of coping with that doubt. Resolving the tension between an emerging constructivist, interpretivist view of the mind and the increasingly disturbing implications of that view for strongly held beliefs in multiple domains of knowledge is one of the principle developmental tasks of adolescence and the focus of this encyclopedia article.

Systematic, generic doubt about the underpinnings of deeply held beliefs – as evident within the relativist or multiplist level – would not be possible without a view of the mind as active in the process of knowing, and a view of knowledge as the product of a dynamic, interpretive, constructive process – meaning as made, not found. It stands to reason, then, that the epistemic misgivings of adolescence must be based on a view of knowing that departs significantly from the absolutist and objectivist view, which characterizes the initial stage in adult models of epistemic development (Chandler, 1987; Chandler et al., 1990). While higher order insights into how knowledge is constructed by the knower may well be dependent on the explicit and formal treatment of theories, paradigms, and perspectives that is a unique part of a college curriculum, it is equally clear that a basic appreciation of the active role of the knower in the acquisition of knowledge predates early adulthood, and even adolescence, and emerges gradually across the middle childhood years (Carpendale and Chandler, 1996; Pillow and Henrichon, 1996; Reich et al., 1994; Smith et al., 2000). According to multiple accounts, it is at 6 or 7 years of age that children first show evidence of appreciating that when information about an event or object is ambiguous or incomplete, an individual's beliefs will be influenced by (i.e., reflect bias from) prior experience, expectations, and self-interest (Mills and Keil, 2005; Pillow, 1991; Pillow and Henrichon, 1996; Pillow and Mash, 1999). Further, children of this age are starting to appreciate, in rudimentary ways, how cognitive processes such as inference and planning can give rise to beliefs (Pillow, 1995).

Although some researchers have argued that a constructivist view of knowing may have even earlier origins (Perner, 1991), the evidence is questionable. For example, while 4-year-olds recognize that beliefs are representations of reality and can differ from that reality, as evident from their success on false-belief tasks, they generally view beliefs as originating in perception – not in cognitive processes of interpretation. Thus, older preschool children recognize that if an individual does not have perceptual access to an event, they will have inaccurate beliefs about that event. However, success with false belief is not sufficient to ensure an appreciation of how individuals with equal perceptual access can, nonetheless, arrive at different and equally legitimate interpretations of objects and events (Carpendale and Chandler, 1996). The emergence of the latter appreciation seems best located in the initial period of middle childhood.

The emergent constructivism of the early school years is extended as children begin to reflect upon and make comparisons across cognitive activities, identifying similarities and differences regarding the properties and function of these activities. Ten-year-olds tend to overlook several cognitive processes involved in the acquisition of knowledge when categorizing mental process verbs (Schwanenflugel et al., 1994). This indicates that while children of this age may consider the interpretive role of the mind in the manipulation of information once it is acquired, they do not fully appreciate the minds' equally important interpretive role in knowledge acquisition. Older children, on the other hand, do appreciate the importance, and potentially interpretive roles, of comprehension, selective attention, and recognition in knowledge acquisition. We also see a significant change from 8 to 11 years in the dimensions children employ when comparing and categorizing mental processes. By the end of this period, children are placing significant importance on a mental activity's likelihood of resulting (or not) in certain knowledge (Schwanenflugel et al., 1996, 1998). The growing focus on the certainty–uncertainty dimension is evident in the distinctions children begin to make during these years between deductive (certain) and inductive (uncertain) inference and between weak and strong forms of induction (Moshman, 2004). This new-found concern with degrees of certainty, and a growing awareness that knowledge claims can be uncertain and solutions to knowledge problems indeterminate, indicates that children are coming to recognize the possibility and legitimacy of alternative meanings in rational inquiry (Pillow and Pearson, 2009; Schwanenflugel et al., 1996).

As children approach and move through preadolescence, their emerging constructivist account of the mind leads to

a new kind of dualism that Chandler (1987; Chandler et al., 1990) label 'defended realism.' This represents an initial attempt to maintain the advantages of an absolutist or objectivist epistemology – namely, an assurance that some knowledge is certain and some controversies resolvable – while acknowledging mounting evidence of uncertainty regarding a variety of knowledge claims. In this phase, children implement a kind of bifurcation of experience. In certain domains, such as religion, where it becomes clear that disputes are not the result of limitations regarding access to objective fact, controversies are regarded as unresolvable and a matter of individual preference and opinion. Such domains come to be regarded as arenas for opinion, rather than fact, and for an appreciation of multiple perspectives, rather than truth (Chandler et al., 2002). Other domains come to be viewed as 'objective' and continue to be protected from significant epistemic doubt. However, as sources of bias in these self-declared objective domains become increasingly apparent, the basis for the split is progressively undermined.

The phase of defended realism coincides with the period of concrete operational thought (Inhelder and Piaget, 1964) and the limitations of concrete operations when it comes to generalization and abstraction mean that epistemic doubts, when they arise, tend to remain situational, and isolated to particular cases (Chandler et al., 1990, 2002). In addition, implications of the fallible nature of a particular belief for other beliefs to which it is related in semantic or episodic memory are not recognized. These cognitive limitations of concrete operations tend to prevent epistemic doubt from fully undermining the dualism of defended realism. With the advent of formal operations (Inhelder and Piaget, 1958), however, a deeper appreciation of the logical implications of constructivism emerges and a more generic and systematic form of epistemic doubt develops (Chandler et al., 2002). Because formal operations are operations upon operations – a meta level of operativity – doubt now becomes more principled, systematic, and potentially endemic to all acts of knowing. The dualism of defended realism is not likely to survive the onset and consolidation of formal operational thought. In addition, the new reflective capacity made possible by formal operations – particularly the capacity to reflect on the knowing process (Chandler et al., 1990; Kuhn and Franklin, 2006) – contributes to an appreciation that subject and object are split in inherently unbridgeable ways.

The emergence of a thoroughly systematic and generic epistemic doubt in the adolescent years, following closely upon the emergence of formal operations, is a significantly under-researched aspect of adolescent development. Nonetheless, available evidence suggests that the prevailing adolescent response to this pervasive doubt initially involves elements of both skepticism and dogmatism (Chandler, 1987), possibly intermixed in the same position. This apparent functional equivalence of seemingly opposite attitudes is important. Although diametrically opposed, skepticism and dogmatism are each an adaptation to epistemic doubt from within an operating assumption that rationality requires certainty and determinacy. Skepticism is a full-on acceptance of the logical implications of constructivism, while dogmatism is a 'leap of faith' to investing certain authority figures with 'better reason to know' (Chandler et al., 1990: p. 380) than the adolescent. Because rationality remains tied to certainty and determinacy in adolescent skepticism, the rejection of the possibility of certain knowledge and of fully resolvable disputes and controversies is also a rejection of the possibility of any rational basis for deliberation and choice. Consequently, this adaptive skepticism is associated with decision-making strategies of a distinctly noncognitive nature, including impulse (the avoidance of cognition), intuition, and conformity (Chandler, 1987). Adolescent dogmatism involves an identical assumption about the dependence of rationality on certainty and determinacy. However, in the case of dogmatism, there is an acceptance of various authority figures as embodiments or sources of the rationality that the doubting adolescent is unable to establish through his or her own cognitive activities. Both these adaptations – skepticism and dogmatism – could be characterized as surrendering control (Bendixen, 2002) of one's beliefs to either noncognitive mental processes (as in the case of skepticism) or external authorities (as in the case of dogmatism). Surrender is to be contrasted with taking ownership of one's beliefs and subjecting them to critique and evaluation. Within skepticism/dogmatism, beliefs are in no need of systematic justification because they are seen as being no less legitimate than the next person's beliefs and/or because they have backing of respected authorities.

Evidence suggests that these adaptations to generic epistemic doubt are extended to the process of identity formation as well. Adolescents in the first level of epistemic development – the absolutist or realist level – as well as adolescents in the somewhat more advanced phase of defended realism, typically score in the diffusion or foreclosure statuses of Marcia's ego-identity typology (Boyes and Chandler, 1992). These two statuses both involve a rejection of the idea that exploration is a necessary precondition for making a commitment to particular values, beliefs, or goals. From the standpoint of an epistemic realism or a defended realism, exploration is arguably irrelevant since it assumes that the evaluation of beliefs and values, for example, is complex and deeply subjective or personal – something that is not consistent with a realist position. Adolescents who have reached the second epistemic level – that of relativism or multiplism – and who also espouse a general skepticism, tend to be in either the moratorium status or the diffused status (Boyes and Chandler, 1992). These statuses share a common lack of commitment. Again, this is consistent with a radical relativism because the latter epistemology allows no basis for making commitments. Finally, there is a clear association between the identity achiever status (exploration leading to commitment) and having attained the rationalist or evaluativist epistemic level (Boyes and Chandler, 1992; Krettenauer, 2005). In particular, longitudinal research shows that the evaluativist position specifically contributes to identity achievement (Krettenauer, 2005).

For many adolescents, particularly if college bound, the skepticism–dogmatism adaptation to generic epistemic doubt gives way to a rationalist or evaluativist

epistemology; the third principle epistemic level, in which doubt is more effectively handled by a commitment to justifying and validating knowledge claims in the absence of certainty. The key to moving into a postskeptical rationalism would appear to be a full appreciation of the notion that there can be rational bases for deciding between alternative claims, even though certainty is impossible and alternative perspectives are irreducibly legitimate. What is the basis for this key insight leading the individual beyond relativism and the paralysis of generic epistemic doubt? One central factor appears to be the progressive development of the skills of rational inquiry and argumentation, something that is itself the result of metacognitive advances associated with formal operational thought, direct instruction in formal educational settings, and opportunities to engage in guided exploration, debate, and discussion (Kuhn and Franklin, 2006). As shown by Kuhn and her colleagues, an appreciation that rationality does not require certainty and determinacy develops as individuals become competent at inquiry and argumentation under conditions of uncertainty (Kuhn et al., 2000a, 2008). Such competence includes the capacity to represent one's beliefs as knowledge claims per se and to consider them independently of potential evidence that might confirm or refute such claims, the ability to generate predictions from knowledge claims and to test such predictions, an appreciation of what can be inferred from the outcome of such tests, and an ability to entertain alternative explanations and counterarguments. In the absence of such competence, alleged facts cannot be elevated to the status of testable claims and therefore, are indistinguishable from opinions, the sole stock and trade of a relativist epistemology.

Is Epistemic Development Recursive or Multidimensional?

As a concluding discussion, let us consider what has been noted above as a fundamentally paradoxical finding in this literature. How can we explain the seemingly contradictory findings that the same developmental sequence of epistemic levels has been found in the period extending from middle childhood through late adolescence and in the years from late adolescence through early adulthood? One possibility, as suggested previously, is that there is more than one pass through this developmental sequence (Chandler et al., 2002). One empirically supported proposal for how and why this might happen concerns the distinction between brute facts and institutional facts proposed by John Searle (1969). Brute facts refer to aspects of our knowledge that do not obviously depend in any essential manner on social conventions, rules, or agreements for their meaning. The structure of a cell, the distance of the Earth from the Sun, or the atomic weight of iron are examples of brute facts. Institutional facts, by contrast, clearly derive their meaning, although not their truth, from particular social conventions, rules, or agreements. An individual's nationality or marital status, the current rate of inflation, and the 1964 convention platform of the Democratic Party are institutional facts. The brute–institutional distinction is problematic in some respects, but it appears to reflect lay intuitions and sensibilities. Evidence suggests that development from the absolutist epistemic level through the evaluativist level occurs earlier for institutional fact domains such as the social sciences than it does for brute fact domains such as the physical sciences (Hallet et al., 2002). This may partly explain the recursive nature of epistemic development. While adolescents are wrestling with epistemic doubt largely, if not exclusively, in regard to institutional facts such as religious and political beliefs, the college years appear to involve the development of similar doubts with respect to brute or physical facts. College also involves a continuous undermining of the brute–institutional distinction, as more and more brute facts come to engender the same element of interpretation and indeterminacy that the individual has already come to recognize in institutional facts.

There is an alternative explanation for why we find the same sequence of epistemic levels at two different developmental periods. The appearance of recursion may be misleading and could be produced by changes in relatively independent epistemic dimensions, and in their interrelationships, from preadolescence through the college years. Some researchers have proposed an alternative to the unidimensional, stagelike models of epistemic development discussed above. Schommer (1998) and Hofer (2004), for example, have proposed multidimensional models. In this view, naïve epistemology could be thought of as a system of distinct but interrelated dimensions or factors (Schommer, 1998). Some dimensions may emerge earlier than others, interrelationships among dimensions may change systematically with development, and there may be substantial individual differences in the pathways or end points of development for these dimensions (Schommer-Aikins, 2004). Each of these possibilities could lead to one distinct set of advances occurring before late adolescence and another relatively distinct set occurring across the early adult years.

Although the multidimensional approach has generally been concerned with the study of individual differences in epistemic beliefs, rather than development per se, some findings within this approach suggest developmental trends that might, ultimately, explain the paradox of apparent recursion across developmental periods. Schommer-Aikins and colleagues (Schommer-Aikins et al., 2000, 2005) report that middle school students' epistemic beliefs appear to be multidimensional, but have a simpler structure than found among high school and college students. In addition, coherent beliefs about knowledge acquisition (e.g., whether learning is an automatic or an effortful process) appear to emerge in advance of beliefs about the nature of knowledge (e.g., whether knowledge is simple or complex, permanent or revisable). The multidimensional approach has also provided evidence that an uncritical reliance on experts, textbooks, and other external sources of knowledge is more prolonged than a similarly uncritical reliance on personal experience as a source of knowledge (Conley et al., 2004; Greene et al., 2008).

Conclusions

Naïve beliefs about the nature of knowledge and knowing – epistemic beliefs – are present from childhood onward and undergo development through a relatively fixed sequence of levels from realism through relativism to rationalism. Although there appears to be more than one pass through this sequence, the hallmarks of relativism as experienced during adolescence include a unique, and possibly prolonged, period of generic epistemic doubt during which the individual comes to question whether there can be any rational basis to deeply held beliefs and values. This doubt is manifest, somewhat paradoxically, in forms of skepticism and dogmatism and has significant implications for other areas of development such as identity formation. The road out of this radical relativism appears to require the key recognition that there are rational bases for holding particular beliefs and for preferring one side in a dispute despite the fact that uncertainty and indeterminacy are endemic to all forms of knowing.

Epistemological Beliefs and Motivation

Abstract

For the last three decades researchers have studied beliefs about knowledge and knowing and their impact on learning. These so-called epistemological beliefs form a complicated and intricate system of beliefs. They not only influence academic performance or information processing but also interact with constructs like achievement motivation. This article will give a brief introduction into the research concerning epistemological beliefs and provide an overview on studies concerning their relation to achievement motivation.

Introduction

Many factors determine how we learn and influence our subsequent performance. Confidence in our own abilities, the knowledge we already have about the learning task, our goals – these factors are some of the major influences widely discussed within literature. For the last three decades, research in education and psychology has taken another factor into account: Beliefs about knowledge and knowing, also known as epistemological beliefs.

These beliefs become salient in a variety of educational experiences: Whenever individuals encounter new information they have to understand, evaluate, or integrate into their existing knowledge, the beliefs they hold about the structure and stability of knowledge or about the justification for their knowing are activated. Individuals have to explicitly or implicitly answer the questions, how they do know what they know and how to choose what and whom to believe (Hofer, 2001). For these answers they tap into their beliefs about knowledge and knowing, which they have both formally and informally acquired. Epistemological beliefs have been linked to various aspects of learning, such as strategy use, reasoning, academic performance, information processing, and motivation. Personal epistemology consequently plays an essential part in learning, yet it has proven to be a rather complicated construct. This is apparent in the number of constructs defined and used to assess personal epistemology, such as epistemological reflection (Baxter Magolda, 2004), epistemic cognition (King and Kitchener, 1994), or epistemological understanding (Kuhn et al., 2000).

The diversity is owed to diverging ideas about which aspects to include within personal epistemology and which aspects to exclude as associated but distinct constructs. Research has called for holistic approaches to personal epistemology, taking further aspects of cognition into account. "The need for an embedded systemic model of epistemological beliefs, that is, a model that includes many other aspects of cognition and affect, comes from the assumption that epistemological beliefs do not function in a vacuum. Indeed, at any given moment, learners' thoughts, actions, or motivations represent the convergence of multiple systems" (Schommer-Aikins, 2004). Although research on such connections is still in its infancy, on motivational grounds auspicious studies exist, which promise that research on epistemological beliefs could shed a new light on the foundations of achievement motivation. The purpose of this article is to give a brief introduction into the research concerning epistemological beliefs and to provide an overview on studies concerning their relation to achievement motivation.

Perspectives on Epistemological Beliefs

The exploration of questions concerning the nature and justification of knowledge has originated in the philosophical discipline of epistemology. The beliefs and theories that individuals hold about knowledge and knowing are subsumed by the terms epistemological beliefs, epistemic beliefs, or personal epistemology. The different conceptualizations vary with regard to their dimensions and boundaries, context sensitivity, and relationship to a variety of cognitive learning outcomes as well as their normative implications in educational settings. The following sections provide a brief overview of the main approaches following essential questions regarding the existing models, the development, the universality, and specificity of epistemological beliefs as well as questions about measures for epistemological beliefs and normative implications of the construct.

How Are Epistemological Beliefs Modeled?

Perry (1970) was one of the first to study individuals' epistemological beliefs as part of an attempt to understand how students interpreted their pluralistic educational experiences. His theory of epistemological development became the basis of a vast variety of studies and approaches concerned with individuals' personal epistemologies. In Perry's model of intellectual and ethical development, personal epistemology is unidimensional and develops from a dualistic perspective on knowledge and the world (being either right or wrong) via the beginning recognition of diversity and uncertainty toward a focus on responsibility and commitment within contextual relativism. At the developmental endpoint the self is perceived as an active maker of meaning and is in need to choose and affirm its own commitments (Hofer and Pintrich, 1997). Perry's research has been continued by researchers conceptualizing personal epistemology from a structural and developmental perspective, exploring how individuals interpret their educational experiences, taking aspects of gender into account (Baxter Magolda, 2004).

Extending Perry's scheme to the domain of everyday reasoning King and Kitchener (1994) assessed individuals'

perspectives on knowledge and their conceptions of justification and argument by presenting individuals varying in age and educational background with different ill-structured problems. Their *reflective judgment model* consists of seven stages, organized in three levels of prereflective, quasi-reflective, and reflective thinking. Using interviews, Kuhn developed a model consisting of three distinct epistemological stages ranging from an absolutistic perspective, over a multiplistic toward an evaluativistic perspective (Kuhn et al., 2000). All three models view epistemological beliefs as a unidimensional construct, in which individuals move through the different stages as they develop.

A competing perspective has been introduced by Schommer (1990). She shifted the way researchers understand epistemological beliefs by conceptualizing the construct from a multidimensional perspective, proposing a system of beliefs, in which different epistemological beliefs emerge and develop at different rates. Along with this new asynchronous perspective she introduced a novelty into research, assessing individuals' beliefs through a questionnaire. In her *Epistemological Beliefs Questionnaire* (EBQ) she identified four to five dimensions of epistemological beliefs, each of which is viewed as a continuum, ranging from beliefs about: (1) the structure of knowledge (knowledge consists of isolated bits of information vs knowledge as highly interrelated concepts), (2) the stability of knowledge (knowledge is certain vs tentative and evolving), (3) the source of knowledge (knowledge is handed down by authority vs individually constructed), (4) the nature of knowledge acquisition (learning occurs quickly vs gradual), and (5) the ability to acquire knowledge (intelligence is fixed vs incremental; Schommer-Aikins, 2004). Despite methodological issues (Qian and Alvermann, 1995) as well as further questionnaire developments (Hofer, 2000), Schommer-Aikins' EBQ remains the primary paper-and-pencil assessment of personal epistemology. Most importantly, her approach to the study of epistemological beliefs provided researchers with measures to explore relations with different factors in the learning process. For a more detailed account of the different epistemological models, please read the comprehensive review of Hofer and Pintrich (2002).

How Do Epistemological Beliefs Develop?

Effects of age and education on the development of knowledge beliefs were one of the first factors explored (Perry, 1970). As Buehl (2003) states, it is difficult to differentiate the internal processes of maturation from the effect of educational experiences that individuals encounter during their development. Research suggests that age works as a significant predictor for changes in students' beliefs about learning, whereas education functions as a significant predictor of the sophistication of epistemological beliefs (Schommer, 1998). Although there is little research in younger populations like elementary school-or middle-school students, findings suggest that the structure and specifications of epistemological beliefs become more complex in populations of greater age (Qian and Alvermann, 1995).

How Are Epistemological Beliefs Related to Cognitive Learning Outcomes?

Most of the research on epistemological beliefs in the last 20 years has focused on the nature of students' knowledge beliefs and how these beliefs relate to a variety of cognitive learning outcomes. In the most prominent studies higher levels of comprehension, strategy use, and academic performance have been associated with what researchers view as more sophisticated beliefs about knowledge (Schommer, 1998; Kardash and Howell, 2000). Advanced epistemological beliefs have been linked to higher levels of information processing (Kardash and Scholes, 1996) and conceptual change (Qian and Alvermann, 1995).

How Specific Are Epistemological Beliefs?

An ongoing debate within research concerns the question whether epistemological beliefs have to be conceptualized as domain specific or domain general. In a host of studies, knowledge beliefs are assessed without being contextualized in a specific field or domain of knowledge (Schommer, 1990). Contrasting, there are researchers exploring the structure of epistemological beliefs within or between distinct academic domains by using domain-specific questionnaires developed to deliberately tab epistemological beliefs with regard to specific subjects like mathematics or history (Buehl et al., 2002). Another strand of research administers the same questionnaire to students of different domains (Jehng et al., 1993) or to the same students, asking them to answer the same questions with regard to two different domains (Hofer, 2000). According to these studies, college students majoring in 'soft' domains hold more sophisticated epistemological beliefs than students majoring in 'hard' fields. Research suggests that students possess general as well as domain-specific epistemological beliefs and that these beliefs are interrelated. Some researchers therefore suggest a multilevel conception of epistemological beliefs (Trautwein and Lüdtke, 2007) in which domain-specific beliefs could be conceptualized as an 'applied form' of general beliefs.

How Are Epistemological Beliefs Measured?

The quality of instruments used to measure epistemological beliefs is the center of a critical debate within research (Bromme, 2005; Trautwein and Lüdtke, 2007). One way of assessing epistemological beliefs is by using open-ended or half-structured interviews, like the *Reflective Judgment Interview* (RJI) developed by King and Kitchener (1994). Although research has found satisfactory internal consistency for the RJI (Wood, 1997), these measures are not suitable for large samples due to the extensive and complex coding involved in their usage. Paper and pencil measures based on the EBQ (Schommer, 1990) therefore form the basis of most research in psychological and educational contexts. Items are generally based on global and decontextualized statements like "Scientists can ultimately get to the truth" (Hofer, 2000). The validity of such global measures is questioned by a variety of researchers. They claim that it remains unclear, what frame of reference individuals choose when evaluating these global statements (Bromme, 2005).

In addition, epistemological beliefs influence learning and thinking in a variety of forms, as they can function as declarative or procedural knowledge – explicit and directly assessable for the individual – or as tacit or implicit knowledge. As

Buehl and Alexander (2006) point out, these different forms of knowledge beliefs coexist and interact in complex ways. Epistemological beliefs are therefore referred to as "socially shared intuitions about the nature of knowledge and learning" (Jehng et al., 1993) or 'informal knowledge' (Elby and Hammer, 2001). So far no reliable instruments have been developed to measure implicit dimensions of epistemological beliefs.

How to Deal with the Normative Implications of Epistemological Beliefs?

Research on epistemological beliefs is intertwined with normative perspectives. Within the unidimensional approaches, epistemological beliefs have been categorized in a continuum of ongoing development with higher stages of development pointing to a somewhat superior epistemological understanding. Within her multidimensional model Schommer-Aikins (Schommer, 1990) introduced a distinction between 'naïve' and 'sophisticated' stances with regard to each of the proposed belief factors. With regard to the cultural dependency of epistemological beliefs it is important to note that current models conceptualize the endpoint of epistemological development in a formative and abstract way of thinking, which has to be understood as a normative characteristic of Western cultures: The ideal of a stronger individualism in thinking, freeing thought from the dictation of authority is a symbol of an individualistic and Westernized socialization. In collectivistic cultures, in which the perspective on the self has interindividual implications, epistemological development might turn toward positions propagating an acceptance of consensus instead of a thinking that strives to be increasingly independent (Cobern and Loving, 2008).

Furthermore the exploration of the relation between epistemological beliefs and different factors in the learning process has led to normative assumptions. Higher levels of strategy use, comprehension, and academic performance have been associated with what researchers view as sophisticated epistemological beliefs (e.g., knowledge is tentative, complex, and derived from reason). As a consequence, a research strand has developed, that explores which forms of education might foster sophisticated epistemological beliefs. However, some research suggests that the connection is not always linear with students sometimes expressing less advanced epistemological beliefs as they gain knowledge in a domain (Trautwein and Lüdtke, 2007). According to Elby and Hammer (2001) researchers have failed "to distinguish between the correctness and productivity of an epistemological belief." A belief should be viewed as productive "if it generates behavior, attitudes, and habits that lead to 'progress' as defined by the given person or community" (Elby and Hammer, 2001, p. 555). Bromme et al. (2008) suggest that *sophistication* should be conceptualized as flexibility of epistemological judgment with regard to differences between contexts. Research should consequently account for the grade of adaptivity or advancement. Following this perspective, epistemological judgments are generated by the interplay of epistemological beliefs, ontological knowledge, and topic-related knowledge as well as the person's ability to account for the demands of a context. Bromme et al. (2008) suggest a new perspective on the adaptivity of epistemological beliefs introducing the idea of the 'division of cognitive labor': Individuals can display an adaptive epistemological understanding without having a fully elaborated understanding of the topic or its underlying ontological assumptions, if they can make out who could give reliable information on a topic and how one could distinguish between competing sources of knowledge claims.

The Relation of Epistemological Beliefs to Achievement Motivation

Over the last decade there have been suggestions that it is necessary to view personal epistemology in a broader context and to explore its relation to achievement motivation (Hofer and Pintrich, 1997). Achievement motivation refers to motivation in situations related to an individuals' competence and achievement-related behaviors (Nicholls, 1984). The relationship between personal epistemology and achievement motivation can be viewed from two angles: One line of research examines the influences of epistemological beliefs on constructs within achievement motivation and self-regulation (e.g., Bråten and Strømsø, 2005). The other line focuses on motivational states as mediators of the effect of epistemological beliefs on learning outcomes (e.g., Richter, 2010). For both perspectives only few empirically sound studies exist. The relationship of epistemological beliefs and achievement motivation uses different theoretical motivational frameworks: Following Buehl (2003), research will therefore be grouped into three sections dealing with the relations of epistemological beliefs and goal orientation, achievement values, and competency beliefs, respectively.

Epistemological Beliefs and Goal Orientation

Achievement goal orientation theory represents one of the most influential approaches to academic motivation in contemporary educational psychology and looks at the reasons or purposes students have for engaging in academic tasks. Two types of goal orientations have been differentiated within literature: mastery-goal and performance-goal orientation. Adopting mastery goals (focus on learning, understanding, mastering tasks, and personal improvement) has been related to more effort and persistence in academic work, the use of a variety of learning strategies that encourage deeper information processing as well as the promotion of interest. Research has broken performance goals down into performance-approach goals (focus on the demonstration of a high competence with the purpose to outperform others or attain favorable judgments of competence) and performance-avoidance goals (focus on the demonstration of a high competence with the purpose to avoid any demonstration of incompetence). While performance-approach goals have been linked to more positive consequences for motivation and achievement, avoidance goals lead to maladaptive outcomes like less intrinsic motivation and poorer achievement (Eccles and Wigfield, 2002; Bråten and Strømsø, 2004). Research distinguishes several potential antecedents of goals, ranging from competence-related beliefs (need for achievement, competence expectancy, fear of failure, trait test anxiety) and contextual variables (evaluation practices) to personal factors like gender or implicit theories of intelligence. According to Dweck and Leggett

(1988), mastery goals are more likely to be adopted by students who believe intelligence is malleable (incremental belief), whereas performance goals tend to be adopted by students who believe intelligence is fixed (entity belief).

Hofer and Pintrich (1997) were among the first to suggest that epistemological beliefs may function as implicit theories that can give rise to personal goals in learning. Buehl (2003) gives a more detailed account of this possible relation: Beliefs about abilities and the desire to engage in a learning task depend on the perception of that specific task. In academic contexts, tasks require the acquisition or manipulation of knowledge. Therefore beliefs about knowledge might influence task-perception and thereby influence goal orientation (Buehl, 2003).

This relation has been confirmed by several studies examining the relation of epistemological beliefs and goal adoption, indicating that students with advanced epistemological beliefs tend to adopt mastery goals. Because all available studies used measures based on Schommer's EBQ (Schommer, 1990), results can be grouped in relation to the five dimensions of personal epistemology she proposed.

Several studies suggest that more advanced beliefs in regard to the *structure of knowledge* (students perceive knowledge more as highly interrelated and less as isolated bits of information) relate to a tendency to adopt mastery goals, whereas students with less advanced beliefs more likely adopt performance goals (Buehl and Alexander, 2006; Murphy et al., 2002; Paulsen and Feldman, 1999).

Studies regarding the dimension *nature of knowledge acquisition* also suggest more advanced beliefs (learning occurs gradual and requires effort) being related to the adoption of mastery goals and less advanced beliefs (learning occurs quickly) being related to the adoption of performance-avoidance goals (Bråten and Strømsø, 2004, 2005, 2006; Buehl and Alexander, 2006; Qian and Burrus, 1996). According to Bråten and Strømsø (2004), who examined the long-term adoption of such goals, this predictive pattern was consistent over time. However, few studies report contradictory findings: Murphy et al. (2002) found beliefs about the need for effort to acquire knowledge – which is typically considered to be an adaptive and advanced perspective on knowledge acquisition – to be related to less adaptive goal orientations. Contradictory findings in respect to both described dimensions stem from a study with students in the South Pacific Region by Phan (2008). Less advanced beliefs regarding the *nature of knowledge acquisition* and the *structure of knowledge* were linked to a tendency to adopt mastery goals. Phan (2008) discusses cultural influences as a possible explanation for these unusual findings.

Regarding the dimensions *stability of knowledge* and *source of knowledge* similar patterns of results were shown as have been reported for the two dimensions described above. Several studies describe more advanced beliefs like perspectives of knowledge being tentative and evolving as well as beliefs of knowledge being constructed by the individual as related to mastery-goal orientation. Less advanced perspectives in regard to the *stability* and *source of knowledge* (knowledge is certain, knowledge is handed down by authority) were linked to the adoption of performance-goal orientations (Bråten and Strømsø, 2004, 2005, 2006; Chen and Pajares, 2010; Kizilgunes et al., 2009; Phan, 2008; Qian and Burrus, 1996). On top of these diverse findings, evidence from a study by Bråten and Strømsø (2005) shows that different dimensions of epistemological beliefs predicted goal orientation in separate student populations of different academic contexts (business administration vs student teachers). These findings indicate that the relationship between epistemological beliefs and goal orientations might be influenced by contextual factors and might therefore be more complicated than initially assumed.

Regarding the epistemic dimension *ability to acquire knowledge* only few studies exist. Their results are in line with existing research on the relation between implicit beliefs of intelligence and goal adoption, indicating that advanced beliefs (intelligence is incremental) are related to mastery-goal orientation (Phan, 2008; Qian and Burrus, 1996).

The majority of studies support the general notion of more advanced epistemological beliefs being related to mastery-goal orientations across different epistemological dimensions. Because most studies only examined correlational relations between dimensions of epistemological beliefs and goal orientation they allow no claims concerning the causal direction of the relationship. Furthermore single studies indicate that aspects of culture and the learning context might influence the relationship.

Epistemological Beliefs and Achievement Values

One of the factors seen to be influential for students' academic choices within educational motivation research is the value that students attach to specific tasks or subjects. Within expectancy-value theory (Eccles and Wigfield, 2002), students' subjective task value along with their competence beliefs is seen to drive students' achievement behavior. Eccles and Wigfield (2002) distinguish between four components of task value. (1) Attainment value is defined as the personal importance of doing well on a task linked to the possibility of confirming salient aspects of an individuals' self-schema. (2) Intrinsic value can be understood as the enjoyment an individual gets from engaging in an activity linking this value to subjective interest. (3) The contribution of a task to the achievement of future goals is defined as utility value. (4) Finally, cost captures all the negative aspects that come along with engaging in a task. Within the model, it is assumed that achievement values are partly influenced by task-specific beliefs (perception of competence regarding the task and task-difficulty). As epistemological beliefs play an important role within learning, researchers have suggested, that they might contribute to an individual's perception of a learning task, but only very few studies address this relationship. Paulsen and Feldman (1999) report less advanced beliefs regarding the *nature of knowledge acquisition* (learning occurs quick) as well as the *ability to acquire knowledge* (intelligence is fixed) to be negatively correlated with students' achievement values. In a study with college students Buehl (2003) investigated the interconnection of achievement value (as a single construct) and domain-specific epistemological beliefs in the subjects history and mathematics. Advanced beliefs regarding the *structure of knowledge* (knowledge is complex and highly interrelated) and the *source of knowledge* (knowledge has to be constructed and is derived from reason) were related to higher levels of achievement value. On the contrary less advanced beliefs on the *stability of knowledge* (knowledge is certain) in both subjects

were also linked to higher achievement value. Enman and Lupart (2000) studied factors underlying undergraduate students' selection of science majors measuring epistemological beliefs and achievement values. Please note that the objective in this study was to measure epistemological beliefs and achievement value to predict students' choice of science as a major. Therefore the relation of both constructs was not the focus of this study. Enman and Lupart (2000) report that less advanced beliefs on the *ability to acquire knowledge* (belief in fixed ability) predicted if students selected science as their favorite subject and choose science as their major. Following Buehl (2003) 'choice of favorite subject' can be understood as a proxy for achievement value. Thereby this study can be interpreted as support for a link between less advanced beliefs on the *ability to acquire knowledge* and higher levels of achievement value.

All in all there is not enough empirical evidence to allow clear statements about the relationship of epistemological beliefs and achievement values. The described studies indicate that the interconnection might be complicated, as they show a mixture of advanced and less advanced knowledge beliefs being connected to higher levels of achievement value.

Epistemological Beliefs and Competency Beliefs

Individuals' achievement choices are not only driven by the values that individuals attach to specific tasks, but also by their beliefs about their own competency. Eccles and Wigfield (2002) point out competency beliefs as directly related to the question "Can I do this task?". Individuals' beliefs about their own competency can relate to their assessments of their ability to organize and execute the courses of action required to produce specific given attainments (*self-efficacy*) as well as to their beliefs about their ability to successfully master certain tasks in the future (*expectancy for success*; Eccles and Wigfield, 2002). Individuals who have strong beliefs about their own competencies show higher achievement and greater motivation and persistence toward challenging tasks (Eccles and Wigfield, 2002).

Individuals' competency beliefs (such as *self-efficacy* and *expectancy for success*) are seen to be influenced by ability beliefs as well as mastery experiences. These two factors are especially interesting in relation to epistemological beliefs, as they are based on student's perception of the task demands. Students' epistemological beliefs can be understood as an aspect of students' perception of the learning task (Buehl, 2003). Therefore students' judgments about their capabilities in reference to a learning task could be partly based on their conceptions of knowledge and how it is gained. Within the formation of self-efficacy and expectancy beliefs, these conceptions of knowledge and experiences with knowledge acquisition might influence students' perceptions of their abilities.

Only little research exists on the relationship of epistemological and competency beliefs. Results of several studies show that more advanced beliefs about the *source of knowledge* (knowledge is constructed) were positively related to self-efficacy and expectancy for success (Bråten and Strømsø, 2005; Chen and Pajares, 2010; Buehl, 2003). Conflicting to these findings Kizilgunes et al. (2009) report more advanced perspectives like beliefs that knowledge comes from reasoning, thinking and experimenting to be connected to lower self-efficacy, whereas less advances beliefs (knowledge being handed down by authority) were related to higher levels of self-efficacy.

Regarding the epistemological dimension *stability of knowledge* similar contradictory findings exist: Whereas most studies report less advanced beliefs about the *stability of knowledge* as negatively related to self-efficacy (Bråten and Strømsø, 2005; Chen and Pajares, 2010) and advanced beliefs as related to higher levels of self-efficacy (Kizilgunes et al., 2009; Phan, 2008), the opposite relationship was reported by Buehl (2003). In her study on domain specific epistemological beliefs in the subjects mathematics and history, less advanced beliefs on *the stability of knowledge* in mathematics or history were related to greater confidence in competency.

Results of several studies indicate a negative correlation of self-efficacy with less advanced beliefs about the *structure of knowledge* (knowledge exist in isolated bits and pieces; Neber and Schommer-Aikins 2002; Paulsen and Feldman, 1999), whereas more advanced perspectives on the interrelatedness of knowledge were positively correlated with self-efficacy (Buehl and Alexander, 2006) and expectancy for success (Buehl, 2003). Here Phan (2008) reports contradictory findings and discusses influences of culture as a possible explanation for the results.

Regarding the epistemological dimension *nature of knowledge acquisition* studies suggest more advanced beliefs (learning is a gradual and effortful process) to be related to higher levels of self-efficacy (Bråten and Strømsø, 2005; Buehl and Alexander, 2006). Similar findings were reported for more advanced beliefs on the *ability to acquire knowledge* (intelligence is incremental) and their relation to higher levels of self-efficacy (Bråten and Strømsø, 2005; Phan, 2008; Paulsen and Feldman, 1999).

All in all knowledge about the relationship of the various dimensions of epistemological beliefs and competency beliefs is based on a thin empirical basis and shows an inconclusive pattern. In tendency results indicate that more advanced knowledge beliefs are related to higher levels of self-efficacy, but contradictory findings exist. These results lead to the notion that the relationship under study might be complicated and possibly influenced by further factors. Supporting evidence for this interpretation comes from Bråten and Strømsø (2005). In their study different dimensions of epistemological beliefs predicted self-efficacy in student populations from two different academic contexts: Less advanced beliefs on the *nature of knowledge acquisition* as well as on the *ability to acquire knowledge* negatively predicted self-efficacy in student teachers. Epistemological beliefs concerning the *source of knowledge* as well as beliefs concerning the *stability of knowledge* predicted self-efficacy in business administration students. This suggests that the relationship between epistemological beliefs and competency beliefs might be influenced by contextual factors.

Discussion

The existing research in the cross-section of personal epistemology and achievement motivations suggests possible connections between constructs. Findings also indicate that the relationship is intricate and complex: Although most

empirical evidence points toward a linear relationship between the constructs, not all studies support this claim.

Regarding the relationship of epistemological beliefs with goal orientation findings suggest that more advanced knowledge beliefs are related to more adaptive goal orientations like mastery or performance-approach goals. Due to the mainly correlational relations, no secure claims concerning the causal direction of the relationship can be drawn. Nor do these studies allow precluding the possibility of an external third variable connecting the two constructs. Despite these limitations present findings suggest that epistemological beliefs could be added to the list of antecedents of achievement goals, thereby broadening the understanding of goal formation. It is left to future research in this field to explore the interplay between the diverse constructs known to affect goal formation. Further research is also required to explore the differential effects of specific dimensions of epistemological beliefs on goal adoption, which may even be influenced by cultural factors (Bråten and Strømsø, 2005, 2006; Phan, 2008). In reaction to their results of different epistemological dimensions have changing importance for goal orientation of students of different academic domains, Bråten and Strømsø (2005) suggest that differences in instructional practices might foster importance of certain epistemological perspectives for individuals. These differences in the way students' epistemological beliefs operate across academic domains could have instructional implications, which should be explored in future research (Bråten and Strømsø, 2005).

For the relationship of epistemological beliefs and achievement values only few studies exist. Although present studies suggest that epistemological beliefs might be related to achievement value, there is more research needed to allow reliable conclusions about the nature and direction of that relationship.

Research on potential relations of competency beliefs and epistemological beliefs do not allow causal claims about the direction of the relationship. Chen and Pajares (2010) make careful interpretations of their findings, suggesting that beliefs about learning and ability may be antecedents to epistemological beliefs. This idea is in line with a hypothesis by Hofer and Pintrich (1997) assuming that beliefs about knowledge and knowing develop rather late within adolescence, whereas beliefs about ability and learning are formed relatively early in childhood. Future research will be needed to address the relationship and possible developmental implications between epistemological beliefs and competency beliefs, exploring if the relationship changes as a function of maturation or educational experience.

Conclusion

Epistemological beliefs are a complicated but central construct in respect to learning that has only been explored for a couple of decades. In this article, epistemological beliefs have been introduced as beliefs about the structure and stability of knowledge and about the justification for knowing, which are formally and informally acquired in the process of socialization and enculturalization. They become salient whenever individuals encounter new information they have to understand, evaluate, or integrate into their existing knowledge. One central aspect in regard to epistemological beliefs is the normative perspective embedded in the construct. The distinction of more 'sophisticated' versus 'naive' stances in regard to knowledge beliefs was clearly constructed from a viewpoint of western cultures, transferring the ideal of a stronger individualism in thinking into the classification of knowledge beliefs. Lately there has been a shift in looking at these normative implications with researchers suggesting focusing on the 'productivity' (behavior or attitudes, that lead to 'progress' as defined by the given person or community; Elby and Hammer; 2001) or 'adaptivity' (Bromme et al. 2008) of epistemological beliefs. Following the perspective formulated by Bromme et al. (2008), *sophistication* should be conceptualized as flexibility of epistemological judgment with regard to differences between contexts.

Effects of epistemological beliefs on a variety of cognitive learning outcomes such as strategy use, reasoning, academic performance, information processing and motivation have been studied in the last decade. Research from this last strand concerning the relationship of epistemological beliefs and achievement motivation has been the center of this article. As outlined in detail above, existing evidence in this field indicates a somewhat linear relationship between the constructs with more advanced knowledge beliefs being related to more adaptive motivational states. Not all studies support this claim though, suggesting the opposite connection of less advanced epistemological beliefs with more positive motivational states and thereby reinforcing questions concerning the 'productivity' or 'adaptivity' of epistemological beliefs in respect to learning.

In a more general approach to the question of possible relations between achievement motivation and personal epistemology, Bråten and Olaussen (2005) explored how certain distinct student motivation profiles drawn from measures of personal interest, mastery goal orientations, task-value beliefs, and self-efficacy are related to epistemological beliefs. Their results showed distinct motivational cluster groups with differences in regard to students' epistemological beliefs. Students with higher levels of motivation and self-efficacy showed a tendency to hold more advanced knowledge beliefs. Although no causal conclusion can be drawn from this study, Bråten and Olaussen (2005) interpret their results as support for the theoretical claim that epistemological beliefs may be important for academic motivation.

Despite the great need for further research, findings so far indicate that epistemological beliefs may offer educators an additional means to influence students' motivation and achievement. Based on their longitudinal study, Bråten and Olaussen (2005) suggest that the relationship between dimensions of personal epistemology and academic motivation is relatively stable over time. They therefore conclude that students, whose academic motivation rises over time, may be supported in this enhancement through more advanced epistemological beliefs. Taking up the discussion on normativity in reference to Elby and Hammer (2001), this could also require focusing on those epistemological beliefs, which have proven to be most 'productive' in supporting certain motivational components like achievement goals or task value.

Would this untested possibility be confirmed, positive motivational states could be supported through fostering of the 'right' epistemological beliefs. The downside of this claim is that studies exploring the conditions involved in epistemic change are still in their infancy. Researchers are only starting to explore central factors in the development of epistemological beliefs.

Bendixen and Rule (2004) discuss 'personal relevance' as a possible condition for change of epistemological beliefs, including topic interest, emotional involvement, and high self-efficacy as factors within this condition. This points toward the circular relationship between epistemological beliefs and motivational constructs already mentioned in the outline of this article. To shed light into this complicated and intricate system of constructs will be a major but promising challenge for future research in the field of motivation and epistemological beliefs.

Equality and Inequality: Legal Aspects

Susan Sturm, Columbia Law School, Columbia University, New York, NY, USA

Published by Elsevier Ltd.

Abstract

Law's role in advancing equality remains a focal point of attention and controversy in both theory and practice. Many of the recurring disagreements in case law, commentary, and politics can be traced to different theories of inequality, informed by differing conceptions of law's role in its remediation. These theories, in turn, reflect differences in the underlying assumptions about the causes of inequality, the continuing significance of identity and discrimination, the appropriateness of considering race and other social categories in remedying inequality, the appropriate balance between inequality and competing values, and the legitimate role of courts and the state more generally in addressing social problems. Courts in the United States and the European Union increasingly use equality theory to police the boundaries of efforts by other public and private actors to address persistent inequality, particularly racial inequality. This article lays out four major approaches to inequality and how they operate differently in judicial and nonjudicial venues: (1) formal inequality of treatment, (2) structural inequality, (3) outcome inequality, and (4) inequality of access. It includes discussion of novel equality theories that have emerged in legal arenas outside the courts and identifies theories designed to reduce the conflict between equality as defined by the courts and nonjudicial bodies pursuing policies aimed at reducing inequality.

Law's role in advancing equality remains a focal point of attention and controversy in both theory and practice. Explicit exclusion based on race or gender from employment, education, voting, and housing has become widely viewed as morally unacceptable and less common. Yet we live in a world of increasing inequality, one in which a widening income, wealth, health, and opportunity gap intersects with age-old inequalities along racial, gender, ethnic, disability, immigrant, and age lines (Sturm, 2014; Massey, 2007; Sharkey, 2013; Wilkinson and Pickett, 2009). That inequality persists in many significant domains – employment, housing, education, wealth, criminal justice – is uncontroversial. Nonetheless, the legal relevance and actionability of enduring and embedded inequality remains highly contested.

Many of the recurring disagreements in case law, commentary, and politics proceed from the clash between theories of equality, tied to differing conceptions of law's role in its remediation. These theories in turn reflect differences in the assumptions about the causes of inequality, the continuing significance of identity and discrimination, the appropriateness of considering race and other social categories in remedying inequality, the appropriate balance between inequality and competing values, and the proper role of courts specifically and the state more generally in addressing social problems.

The meaning of inequality and scope of remediation also vary depending on the locus of the body elaborating equality norms and remedies. Judicial, legislative, administrative, and nongovernmental bodies have differing conceptions of legitimacy, authority, and state power, and those differences affect the way they engage with issues of equality. In the US and European Union (EU) jurisprudence, courts applying equality principles use equality theory to police the boundaries of efforts by public and private actors to address persistent inequality through explicit and direct action requiring differential treatment, particularly, racial inequality. Most recently, commentators and policy makers have begun exploring frameworks that locate equality within a broader normative framework, decenter the role of the judiciary in advancing equality and embrace hybrid, polycentric strategies for addressing enduring inequality (De Burca, 2006; McCrudden, 1999; Fishkin, 2014; Sturm, 2006a, 2014). This article lays out four major approaches to inequality: (1) formal inequality of treatment, (2) structural inequality, (3) outcome inequality, and (4) inequality of access. It includes innovative theories for reducing inequality that have emerged in legal arenas outside the courts, and identifies theories designed to reduce the conflict between equality as defined by the courts and equality as defined in nonjudicial arenas pursuing policies aimed at reducing inequality. It also contrasts current US antidiscrimination law with more proactive legislative and administrative strategies developing in Europe and in nonjudicial arenas in the US.

Formal Inequality of Treatment

The baseline conception of inequality in the US and EU antidiscrimination law is embodied in principle of equal treatment. The law pursues equality by eliminating race, gender, or other suspect social categories as a legitimate basis of classifying people for the purpose of allocating resources or making decisions (Collins, 2003). Sometimes called the anticlassification principle (Fiss, 1971; Siegel, 2004), formal equality focuses on the state of mind of the decision maker; it targets intentional reliance on race, gender, or another protected category as the violation of the equality norm. It is process oriented, in the sense that it regards the taking account of a person's identity in the treatment of students, voters, employees, prospective homeowners, and people more generally, as both the harm and the wrongful conduct.

The hallmark narrative of formal equality has as its protagonist individuals who deliberately exclude or marginalize other individuals based on their race, gender, sexual orientation, or other protected classification. This model defines the wrongful conduct as intentional, unequal treatment based on race, gender, sexual orientation, age, or some other

class-based characteristic that is viewed as arbitrary. For inequality to count as legally relevant under this theory, it must be demonstrably caused by this form of deliberate, class-based exclusion.

The premise of this model is that race, gender, and other class characteristics are irrelevant to the underlying decision, and that taking class membership into account is thus arbitrary and unfair (Fiss, 1971; Fallon, 1984). The goal of the formal equality model is 'color blindness': decisions affecting people's status and opportunity should be made without regard to social categories such as race or gender. Race, gender, and other categories of status operate as fixed, universal, and static categories based on membership in a set, unchanging group identified by predetermined, and often physical, characteristics such as skin color or sex. The assumption is that group status is, by definition, irrelevant to decisions based on merit, that considering class status is by nature arbitrary, denigrating, and unfair, that decision makers can make decisions without noticing or taking account of racial and gender characteristics, and that equality can be achieved by a rule that prohibits decision makers from considering race or gender.

The formal equality norm rests on a principle of the dignity of the individual. For those who subscribe to formal equality as an umbrella conception, 'stigma' is the crucial element in analyzing racial classifications. As the US Supreme Court recently stated, "To be forced to live under a state-mandated racial label is inconsistent with the dignity of individuals in our society" (Parents Involved in Community Schools v. Seattle School District No. 1, 127 S. Ct. 2738 (2007)). The Supreme Court recently extended its concern with preserving individual dignity and avoiding stigmatization to the context of sexual orientation, invalidating as inconsistent with equality principles a law that "places same-sex couples in an unstable position of being in a second-tier marriage. The differentiation demeans the couple . . . and it humiliates tens of thousands of children now being raised by same-sex couples" (United States v. Windsor, 133 S. Ct. 2675 (2013)). Canadian, French, and the EU law similarly bases prohibitions against disparate treatment on dignitary values, often drawing directly from United States antidiscrimination laws of the 1970s (De Burca, 2012; Moreau, 2010). For example, the European Convention for the Protection of Human Rights and Fundamental Freedoms prohibits discrimination "on any ground such as sex, race, colour, language, religion, political or other opinion, national or social origin, association with a national minority, property, birth or other status," and grounds this equal treatment mandate in the "independent value of respect for individual dignity" (Collins, 2003; Tremblay, 2012). Proponents of formal equality also identify racial polarization as a concern underlying color blindness jurisprudence (Siegel, 2011; Yoshino, 2011): "All state-imposed classifications that rearrange burdens and benefits on the basis of race are likely to be viewed with deep resentment by the individuals burdened. The denial to innocent persons of equal rights and opportunities may outrage those so deprived and therefore may be perceived as invidious" (Regents of the University of California v. Bakke, 438 U.S. 265, 294 n. 34 (opinion of J. Powell)). Formal inequality theory provides remedies to individuals who have been subjected to a process tainted by racial or gender considerations. It is decidedly ahistorical and individualistic in its focus, and compensatory in its explicit remedial approach. Subscribers to formal equality view race and gender as biological or immutable categories that also operate as "a fixed yet radically empty feature[s] of every person's identity" (Siegel, 2000: p. 91). According to this view of race, in particular, the category has no socially relevant content (Siegel, 2000).

Many who embrace a formal equality approach believe current racial inequality results from factors unrelated to racial or gender discrimination, or at least to factors that lie beyond the constitutionally defined boundaries of equality. The election of Barack Obama, a man of mixed Caucasian and African heritage, to the US presidency in 2008 has prompted some conservatives to suggest that the United States has moved to a postcivil rights society, in which race no longer operates in a manner that is actionable through the courts. "Post-racialism is a set of beliefs that coalesce to posit that racial discrimination is rare and aberrant behavior as evidenced by America's and Americans' pronounced racial progress" (Barnes et al., 2010: p. 968). One critical commentator summarized the view that the mechanisms of discrimination can be reduced to a simple paradigm – explicitly discriminatory policies and rogue individuals: "Discrimination is over. The market is bias-free. The law's job is to find the aberrant actor who just didn't get the memo" (Gertner, 2012: p. 111).

Commitment to race blindness is not limited to the US. For example, French law insists on race neutrality and "leaves no room for the possibility of justifying racial distinctions to remedy past racial harms or to promote diversity, as U.S. law does" (Suk, 2007: p. 13). Suk traces the color blindness norm in France in part to conceptions of equality and citizenship that regard social distinctions of any sort as a threat to republicanism (Suk, 2007).

Formal equality embraces the idea that decision makers such as employers and educational institutions may, and usually do, properly differentiate among people based on qualifications relevant to capabilities and performance. By taking social categories such as sex or race into account, decision makers unjustifiably depart from merit-based decision making. This violates basic notions of fairness because people deserve to be treated 'on the merits,' based on an individualized assessment of their capacities (Fallon, 1984; Gutmann, 1996; Suk, 2007). Exclusion based upon characteristics that are beyond the control of the affected individual are viewed as particularly morally problematic (Fiss, 1976; Brest, 1976). Decisions based on class membership thus offend dignitary values, in addition to undermining instrumental values of efficiency. Perhaps the most vehement expression of this view in the US can be found in Justice Scalia's concurring opinion invalidating voluntary affirmative action in government contracting based upon its inconsistency with the principle of color blindness: "To pursue the concept of racial entitlement—even for the most admirable and benign of purposes—is to reinforce and preserve for future mischief the way of thinking that produced race slavery, race privilege, and race hatred. In the eyes of government, we are just one race here. It is American" (Adarand Constructors vs. Pena 115 S. Ct. 2097 [1995]).

Those who embrace formal inequality may disagree about the degree of enduring inequality, but they share skepticism about the legitimacy and efficacy of efforts to address this form of inequality by taking race into account as a factor in allocating

benefits and opportunities to individuals (Rappaport, 2013; Suk, 2007; Browne, 1993; Rabkin, 1997; Sowell, 1984). Courts properly focus on remedying wrongful acts by perpetrators intending to exclude people based on their race, age, sex, or sexual orientation. Efforts to remedy inequality by making race a basis for individual advancement are deeply suspect under this approach. Justice Roberts restates his commitment to the color blindness principle in the context of higher education admissions: "The way to stop discrimination on the basis of race is to stop discriminating on the basis of race" (Parents Involved in Community Schools v. Seattle School District No. 1, 30). Formal equality principles increasingly operate to challenge the legality of efforts to remedy enduring inequality, particularly, in the context of affirmative action, voting rights, school desegregation, and other voluntary state efforts to reduce persistent, group-based inequality. (*see* Affirmative Action: Comparative Policies and Controversies; Affirmative Action: Empirical Work on Its Effectiveness).

Critiques of Formal Equality

The dominance of formal equality in American antidiscrimination law has produced a wide array of criticism. The most prevalent concern proceeds from the observation that color blindness is an inadequate response to continuing inequality. Most fundamentally, critics point out that a formal equality theory leaves intact a legacy of state-produced inequality and subordination. It ignores the role that group status continues to play in shaping the life chances, opportunities, and experiences of group members. It locks in the continued effects of past formal exclusion, imposing the consequences of that continued exclusion on the excluded groups themselves. By defining equality solely in terms of the conduct of the perpetrator, a formal equality approach normalizes conditions of marginalization and exclusion and the group dimensions of these material conditions. It does not begin to address the perspective of those who experience exclusion, marginalization, and unequal enjoyment of resources and status (Crenshaw, 1988; De Burca, 2012; Gotanda, 1991; powell, 2009). At the same time, "It conceals the distributive consequences of group-salient practices in a semantic code that defines instrumentally rational utterances as race-neutral" (Siegel, 2000: p. 101). "Acceding to a worldview on which racial inequity is primarily the product of present bad actors rather than largely a matter of historically embedded hierarchies fosters the misdescription of a central social problem and therefore helps make it less likely that the problem will be addressed through appropriate means" (Primus, 2003: p. 499).

On a conceptual level, David Strauss has pointed out the logical inconsistencies of color blindness as an antidiscrimination principle. To protect a designated group against treatment targeting that group, the state must pay attention to and indeed specially protect the interest of that group. Thus, color blindness is contradictory. Strauss also points out that the metaphor of color blindness really does not fit its use in the nondiscrimination context. Color blindness in the literal sense prevents an individual from seeing color; color blindness as an equality model prevents an individual from acting on what he or she sees. This approach presumes (incorrectly) that individuals can see race but keep it from influencing their perceptions, conduct, and decisions (Strauss, 1986).

Recent work in the social sciences challenges the assumption that conscious decision making adequately describes the current dynamics of exclusion and unequal treatment. Bias is produced not only as a result of motivation but also as a product of racial or gender schemata, multiracial group interactions, unequal access to networks, and patterns of conflict resolution or avoidance (Bagenstos, 2006; Dasgupta, 2004; De Burca, 2006; Krieger, 1995; Sturm, 2001). Bias or exclusion often results from interactive patterns of noninclusion, as much as from exclusion motivated by bias (Sharkey, 2013; Wilkins and Gulati, 1996). Members of nondominant groups may well be treated differently based on their race, notwithstanding the decision maker's lack of intention to do so.

Historians have also challenged the theory of formal equality for its ahistoricism. Color blindness ignores historically constituted patterns of group inequalities that are "socially pervasive (articulated across social domains), and socially persistent (articulated over time)" (Siegel, 2000: p. 82). Examining race and gender inequality from a historical standpoint reveals relations of group inequality embedded in the social organization of work, reproduction, and sexuality (Siegel, 2000). "In actuality, the United States has been plagued with … the consistent use of racial classifications to privilege (certain groups of) whites and disadvantage nonwhites" (Harris, 2000, 2009). The focus on classification itself – because it makes suspect race-conscious action taken to combat racism – justifies the maintenance of existing social and political relations (Harris, 2000). As Kenji Yoshino has noted, "an equal protection jurisprudence that turns formalistically on facial discrimination will, from an antisubordination perspective, get it exactly backward. On the one hand, this jurisprudence invalidates affirmative action programs seeking to aid historically subordinated groups. On the other hand, it upholds second-generation discrimination that continues to subordinate those groups" (Yoshino, 2011: p. 767). Similar critiques have been made of color blindness and equal treatment jurisprudence in Europe, there by yielding more far-reaching adoption of more proactive and structural approaches in the regulatory arena (Suk, 2007; De Burca, 2012).

Robert Post applies this structural account of the dynamics of bias to the law itself. Using what he calls a sociological account of the field, he contends that law does not and cannot cause employers to make judgments about qualifications in a way that is totally race and sex blind. Legal actors are themselves engaged in a social practice of shaping the norms and conventions by which sex and race are given social meaning. "Antidiscrimination law always begins and ends in history, which means that it must participate in the very practices that it seeks to alter and to regulate" (Post, 2000: p. 17). To pretend otherwise is to allow courts to rely on unarticulated assumptions and premises that legitimate some racial or gender meanings and challenge others.

A final critique relates to the threat to the court's legitimacy stemming from the gap between inequality as recognized by law and inequality as people experience it (Sturm, 2006b; Sturm, 2014). As that gap grows, the refusal of law to acknowledge persistent inequality undermines legitimacy of the law as an instrument of justice. This legitimacy deficit is

compounded when the court not only defines equality narrowly but proscribes the role of other branches of government or private entities in identifying and addressing more structural dimensions of persistent inequality.

Similar observations of persistent inequality left unaddressed by antidiscrimination strategies have been made in Europe. However, European and the US antidiscrimination law diverge in their response to these shared critiques of formal equality. Despite the fact that "core concepts and provisions of EU anti-discrimination law … were drawn from the United Kingdom's anti-discrimination law of the 1970s, … [which] were in turn strongly influenced by U.S. law at the time" these legal principles served as a predicate for dramatic expansion of European anti-discrimination laws through "new legislation and treaty provisions, new institutions such as the EU Fundamental Rights Agency, renewed civil society activism" (De Burca, 2012: p. 3). This difference has been traced to a shared European idea that "the provision and promotion of the human and social welfare of their peoples is a core aspect of the responsibility of the states" (De Burca, 2012: p. 7), in contrast with the US legal and political culture, which privileges the idea of individual freedom (De Burca, 2012). It is also possible that these differences stem in part from the fact that "the United States is several decades ahead of the European Union" in the evolution of its antidiscrimination law and policy so that "Europe has not yet experienced the powerful backlash that probably awaits an ambitious program" (De Burca, 2012: p. 10).

Structural Inequality of Treatment

A second approach focuses on structural, situational, and relational dynamics that produce and sustain inequality. Referred to as addressing second, third, and fourth generations of discrimination (Fredman, 2012; Sturm, 2001), this theory provides a framework that continues to account for inequality as a result of unintentional and embedded inequality as well as intentional biased treatment. It broadens the focus of analysis from formal and deliberate decisions to the social context and practices that produce decisions, and from individuals to groups and the contexts that shape their mobility, status, and circumstances.

Structural inequality analyses rest in part on goals similar to those of formal inequality theories: fair treatment and dignity. Differences in treatment between majority and minority group members that are arbitrary, in the sense that they are not justified by criteria of economic rationality, violate this principle of equality. This approach questions the fairness assumption underlying formal equality theory's meritocracy principle to the extent that it presumes that "qualifications are set that are relevant to the legitimate social purposes of the position in question" (Gutmann, 1996: p. 126). If differences in treatment are attributed to stereotyping, cognitive bias, power differentials, or differential access to the networks that structure advancement, they violate this fairness principle, even if the decision maker did not consciously intend that result. The harm is not only the stigma or loss of dignity that results from substituting group characteristics for individual assessment. It is also the difference in access that results from patterns of exclusion that emerge from social interaction or cognitive bias (Directorate General of Human Rights, 2004; Krieger, 1995; Sturm, 1998).

Structural inequality theorists go beyond the individualistic versions of these values to connect equality concerns to consider group-based issues of access and opportunity, and some connect equality values to more basic human concerns of diversity, equity, 'full participation,' 'belonging,' civic agency, and democratic legitimacy (powell, 2012; Sturm 2014). Gender mainstreaming policies in Europe embrace structural approaches to addressing inequality, and define equality positively to mean "an equal visibility, empowerment and participation of both sexes in all spheres of public and private life" in order to promote "the full participation of women and men in society" (Directorate General of Human Rights, 2004: p. 8; De Burca, 2006). They strive for the "(re)organization, improvement, development and evaluation of policy processes, so that a gender equality perspective is incorporated in all policies at all levels and at all stages, by the actors normally involved in policy making" (Directorate General of Human Rights, 2004: p. 12).

Structural inequality conceptions rest on a range of causation theories. One cluster continues to focus on the mind-set of decision makers, but shifts the focus from conscious and intentional bias to unconscious bias and stereotyping. People categorize along racial, gender, and ethnic lines, and these cognitive processes lead us to perceive and judge people differently, in ways that have a direct effect on employment, housing, admissions, and other decisions allocating opportunities and resources (Krieger, 1995; Bagestos, 2009; Sturm, 2001). Though seemingly inconsistent with strict formal equality, the US Supreme Court's opinion in *Hibbs* locates constitutional harm in 'firmly rooted' "stereotype-based beliefs about the allocation of family duties" that operate to the disadvantage of women in "situations in which work and family responsibilities conflict." Policies requiring employers to provide or adjust family leave have been justified as a means "to eliminate their reliance on and perpetuation of invalid stereotypes, and thereby dismantle persisting gender-based barriers to the hiring, retention, and promotion of women in the workplace" (*Hibbs*, 123 S. Ct. at 1981 n.10).

Structural inequality also can include a more institutionally embedded causal theory, focused on ways that inequality resides in the institutions and communities that structure people's lives (McCrudden, 1999; De Burca, 2006). These dynamics are multilevel, crossinstitutional, and nontechnical, embedded in cultures and routines, and often hard wired into policies and structures (Green, 2003; Sturm, 2001, 2014). They occur through cumulative advantages and disadvantages over a long period of time and produce isolation or marginalization from the experiences and relationships crucial to mobility and achievement. john powell has described the 'grammar of durable racial inequality' through the lens of racialization, which means "the set of practices, cultural norms, and institutional arrangements that are both reflective of and simultaneously help to create and maintain racialized outcomes in society" (powell, 2009: p. 785). Structural approaches combine attentiveness to process and outcomes, examining the mechanisms and barriers that

shape whether people of different races have "the wherewithal to succeed, thrive and contribute" and emphasize reflection, capacity building, and networks as strategies for improvement (Sturm et al., 2012; Sturm, 2006b).

This form of inequality is often difficult to identify at the level of individual decisions. For this reason, structural equality of treatment approaches often focus on patterns of unequal treatment affecting groups of similarly situated individuals. Unexplained disparities in treatment of similarly situated members of majority and minority groups are problematic under this approach (*Teamsters vs. United States*, 431 US 324 [1977]; De Burca, 2012; Lenhardt, 2011). Fault, in the sense of conscious intent to exclude based on irrelevant and suspect classifications, is not necessarily a criterion for discrimination.

Structural inequality theorists disagree about the appropriate remedial role of the judiciary, with European law showing more openness to structural definitions of equality at least in some areas (De Burca, 2012; de Witte, 2012). Some commentators in the US advocate expanding judicial doctrine to include unconscious bias and structural discrimination (Green, Krieger). Some question the viability of relying on the courts to define these equality norms. Some have advocated a shift to liberty principles or universalist goals as the appropriate strategy for tackling structural inequality and encouraging cross-racial collaboration (Yoshino, 2011). Others believe the courts retain a more limited but still-significant role in tackling structural inequality – one focused on "prompting—and creating occasions for—normatively motivated inquiry and remediation by non-legal actors in response to signals of problematic conditions or practices" (Sturm, 2006: p. 47; see also Lenhardt, 2011).

Some structural inequality theorists and policy makers have looked beyond the courts to other arenas that have more latitude and capacity to catalyze institutional and systems change, such as administrative agencies and hybrid public/private accountability systems, as locations for reducing structural inequality. For example, Olatunde Johnson has identified a series of federal 'equality directives' in the US that use administrative tools of conditioned spending, policy making, and oversight to promote substantive inclusion with respect to race, ethnicity, language, and disability. These measures require states to take proactive, front-end affirmative measures to address structural barriers to equality (Johnson, 2012). Susan Sturm has documented the role of public/private collaborations that embrace 'full participation' as a way to address structural inequality in particular communities and institutions through public policy aimed at institutional transformation (Sturm, 2014). john powell has put forward the role of law in redesigning policies and systems to connect underserved communities and their residents "to the opportunity structures that improve well-being and pave the path to success" (powell, 2012: p. 19).

In Europe, mainstreaming commissions and administrative bodies have advocated and in some countries embraced far-reaching structural approaches to advancing equality, intended to "change the structures in society which contribute to maintaining the unequal power balances between women and men" (Directorate General of Human Rights, 1998: p. 8). These initiatives locate gender and racial equality within broader principles of democracy and human rights (Directorate General of Human Rights, 2004; De Burca, 2012).

Critiques of Structural Inequality

Some critics question the practicability of this structural move through judicial intervention, given the courts' and politicians' reluctance to go beyond formal inequality as the normative underpinnings of judicial intervention (Bagenstos, 2006; Fredman, 2012). In the US, doctrinal limitations and deference to decision makers such as employers and government bodies, along with recent cut-backs on the availability of class actions, further limit the viability of judicial remedies for structural discrimination (Bagenstos, 2006; Gertner, 2012). Libertarian critics question whether courts should become enmeshed in addressing patterns that are not the responsibility of an individual and are pervasive. If cognitive bias is widespread, indeed, ubiquitous, is it appropriate to rely on the law to change embedded patterns of interaction? (Wax, 1999) Scholars concerned about realizing rights in practice note that this form of bias is embedded in cultures and organizational structures, and courts are limited in their capacity and willingness to disrupt these patterns.

Conservative critics have questioned the viability of a model of discrimination that, by its nature, can only be detected by looking at patterns involving groups over time (Browne, 1993; Rabkin, 1997). Some have also questioned the empirics; they are particularly concerned about extending laboratory-based findings of implicit bias to account for bias in the workplace (Tetlock and Mitchell, 2009; Wax, 1999). Critics from the left have also questioned discrimination theory, particularly unconscious bias, as too limited an explanation because it prompts superficial strategies that leave the underlying structures of durable inequality unchanged (Banks and Ford, 2009; Loury, 2000; Wilson, 1996). Courts themselves are subject to these biases, and are unlikely to find discrimination in the absence of evidence of animus (Gertner, 2012). Unconscious bias discourse "reinforces a misguided preoccupation with mental state, and perpetuates an obsession with antidiscrimination law, rather than policy reform, as a means of realizing racial justice goals … The best political approach, over the long term, is to straightforwardly define and defend policy goals, and then figure out how to achieve them" (Banks and Ford, 2009: p. 1059). Scholars and policy makers have questioned whether structural inequality alone provides a theory of change sufficient to move beyond critique and to construct the institutions and settings that reduce inequality and to enable people who are currently marginalized to thrive (Loury, 2000; Sturm, 2014).

Critics of noncoercive strategies for reducing structural inequality in both the US and Europe also question the robustness of their implementation and their capacity to address durable inequality in arenas that are most stratified and least likely to cooperate in process-oriented equality regimes (Fredman, 2012; Selmi, 2005). The duty to 'have due regard' for equality in Europe or to exercise reasonable care in US sexual harassment cases has been applied with sufficient

deference to public bodies to produce cosmetic rather than substantive change (Fredman, 2012; Krawiec, 2003). There is a fear that gender mainstreaming has been introduced "at the expense of specific measures which focus on long-term, systemic and structural inequalities faced by women in the labour market" (Shaw, 2005: p. 262).

Inequality of Outcome

This concept of inequality focuses on differences in the material conditions of members of particular groups. It is rooted in social reality and looks at the distribution of jobs, income, and status of members of groups that have previously been subjected to systematic exclusion and subordination (Fredman, 2012; Fiss, 1976; Fallon, 1984). The focus of this theory is the group, rather than the individual who has been excluded as a result of group status. Groups continue to matter because they define the opportunity structures affecting their members. For these theorists, group status must be directly addressed because it is the level at which inequality operates. For some, groups also have independent normative value, reflected in the patterns of cultural and political meaning that emerge among individuals who identify as a group (Gotanda, 1991). These theorists justify the focus on groups not only in instrumental terms, but also as an independent value.

The empirical premise of outcome inequality theory is that current inequality continues to be the result of systematic and legally sanctioned subordination. Legal intervention is justified to remedy persistent and arbitrary differences in resources, social status, and opportunity based on group membership. The current system for allocating opportunities continues to reflect biased criteria that systematically disadvantage nondominant groups. Thus, group-based remediation compensates for departures from merit-based decision making (Fiss, 1971; Harris and Narayan, 1994). The goal of this approach to equality is outcome oriented: disparities in group status should be reduced or eliminated. This conception of inequality has also been called the antisubordination principle: the conviction that it is wrong for the state to engage in practices that enforce the inferior social status of historically oppressed groups (Fiss, 1976; Siegel, 2004). Equal outcome theories have been recently advanced through a comparative perspective that contrasts the United States' aversion to quotas with the use of quotas as a way to advance democratic legitimacy in other countries, such as Brazil and France (Suk, 2012).

The normative justifications for the equal outcomes theory are either compensatory and remedial or grounded in theories of democratic legitimacy. Past group-based subordination justifies current group-based remediation. This theory rests on the premise that the group continues to have social meaning. The group continues to experience harm that is a consequence of the history of group-based exclusion, and members of the group experience the current manifestations of that harm. For this reason, matching harm to individual injury is thus both unnecessary and counterproductive (Crenshaw, 1988). Moreover, group-based remediation is necessary to overcome barriers to participation that are perpetuated through facially neutral processes and criteria (Siegel, 2000; Abrams, 1989). Reducing the continuing effects of past group-based discrimination has served as a justification for using affirmative action in employment, requiring preclearance of voting systems, and overturning restrictive voter registration requirements and gerrymandering, which have produced systematic underparticipation of protected groups in the political process (Sturm, 2001; Guinier, 1994).

Other justifications for the outcomes theory of discrimination are more pragmatic: bias is difficult to prove and process rules are easy to evade. Outcome measures serve as an adequate proxy for bias that continues to affect access to fair process and opportunity. If a process is fair and race or gender neutral, it will produce a result that more or less mirrors the composition of the pool (Suk, 2012). Outcome measures that strive for a workforce that mirrors the racial or gender composition of the pool simply accomplish directly what may be more difficult to achieve through reforming the decision-making process. These measures also provide an easy-to-implement remedy that responds to concerns about judicial capacity to detect and correct patterns of bias (Fiss, 1971; Suk, 2012).

Finally, some theorists link representation to theories of democratic legitimacy, drawing on the language relating to diversity to highlight the importance of enhancing parity in representation among groups that have been marginalized from public participation (Suk, 2012). Unlike the US, Europe has shown greater openness to a 'parity democracy' paradigm that uses quotas to increase participation of women in political and corporate decision making, based on an understanding of inequality as a problem of democracy and citizenship (Suk, 2012; Robio-Marin, 2012).

Critiques of Outcome Theories of Equality

Adherents of formal equality criticize outcome-based theories as inconsistent with the principle of race neutrality; they believe it offends dignitary and fairness values by allocating benefits based on an irrelevant and demeaning category. These approaches are seen as advancing quotas, which fail to recognize people as individuals and invite racial polarization and balkanization (Yoshino, 2011; Suk, 2012; Siegel, 2011). Some critics take the view that any approach that treats race or gender as a salient category, even for remediation, reinforces the continued significance of those categories and is thus discriminatory. They also question the appropriateness of remedial strategies that focus on groups. This skepticism proceeds in part from an increasing willingness to question the empirical assumption that current inequality is the result of past legal subordination. Since the 1970s, some scholars have developed alternative explanations for persistent inequality that emphasize characteristics of the racial or gender group, rather than patterns of exclusion or marginalization (Glazer and Moynihan, 1975; Sowell, 1984). Once the causal link between current economic or social inequality and legal exclusion or subordination is questioned, skepticism undercuts the perceived legitimacy of group-based remedies. Indeed, some critics of outcome theories of equality question whether racial or gender status continues to have any meaning at the level of the group. Some conservative critics thus suggest that group-based remediation is just another form of racial or gender-based decision making, and is thus illegitimate

(Clegg, 2013; Belz, 1991; Abram, 1986; Scalia, 2007; Roberts, 2007). Finally, they treat outcome-based equality theories as inconsistent with principles of merit-based decision making and thus contrary to both efficiency and dignitary values (Browne, 1993).

Outcome theories have also been criticized by progressives as an inadequate framework to define equality policy because they rest so heavily on pragmatic considerations and lack an adequate normative foundation. Outcome theorists typically view their strategies as contingent and temporary. They do not generally defend group-based redistribution as an end in and of itself, but rather as a means to an end. Nor do they reveal what it was about current practice that is objectionable, other than the result. The absence of a clearly articulated normative justification invites challenges to the legitimacy of any efforts to address racial or gender bias. Outcome approaches, if used as the exclusive theory justifying equality initiatives, may thus stunt the refinement, rearticulation, and reformation of the normative meaning of racial and gender participation and exclusion. They may also reinforce the perception that equality and efficiency are competing goals (Sturm, 2001; Sturm and Guinier, 1996).

Inequality of Access

Unequal access theories focus on inequalities that result from unfair criteria and structures of interaction. They target decision making that is formally fair but functionally biased in favor of members of a particular group. The central question is whether the structure, process, or criteria of decision making arbitrarily favors members of one group over another for reasons unrelated to the articulated goals underlying the decision (Sturm, 2001).

The most widely articulated conception of equal access theory accepts the moral legitimacy of differentiating among applicants based on meaningful differences in their qualifications to carry out the functions of a position. Reasonable disagreements exist, however, concerning the social purposes relevant to employment or admissions, the relative importance of multiple purposes, and the best way to assess, which applicants meet those qualifications. "Those members of society who now have the power to set qualifications may tend to value those qualifications that favor people similar to themselves" (Gutmann, 1996: p. 124). Moreover, these power differentials shape the structures for assessing individuals' qualifications and opportunities for advancement. These standards and structures are no more likely to produce valued social outcomes than others that do not exclude members of nondominant groups. As such, these exclusionary standards and practices are unfair, and thus discriminatory (Strauss, 1998).

The classic case of *Griggs vs. Duke Power Co.* (401 US 424 [1971]) lays out this theory through a fable: "Congress has now provided that tests or criteria for employment or promotion may not provide equality of opportunity merely in the sense of the fabled offer of the milk to the stork and the fox." Discrimination thus occurs when an employer relies upon conditions, criteria, or practices that favor members of a particular group, if that advantage is arbitrary in the sense that it does not advance the articulated goals of the employer.

This theory defines discrimination as conduct that deprives individuals or groups of meaningful access to educational or employment opportunities through the use of standards, criteria, or structures that fail to minimize the expression of bias, or that arbitrarily advantage one group over the other (Friedman, 1986). It builds on the practical insight that discrimination and inequality often result from arbitrary, unstructured, and unaccountable decision making. It uses outcome measures not to define the harm, but to signal the likelihood that an employment or admission process is biased, and thus to trigger scrutiny of the adequacy and fairness of the criteria and their application. The beneficiaries of this theory are both individuals, who are denied the opportunity to compete based on unbiased selection processes, and groups, which are systematically disadvantaged in their access to jobs or colleges.

Equal access goals have been part of the equality story in the US from the time of the original civil rights act, which at its introduction was defined to assure that, in President Kennedy's words, "public funds, to which all taxpayers of all races contribute, not be spent in any fashion which encourages, entrenches, subsidizes or results in racial discrimination" (Johnson, 2012: p. 26). Olatunde Johnson has documented the adoption 'equality directives' in variety of legal and policy settings, which require public and private actors to examine their practices to identify disparate impact and design inclusionary alternatives (Johnson, 2012).

Equal access theory has thus emerged as an integrative approach to discrimination that accepts the inevitability, if not the legitimacy, of merit-based distinctions but introduces structural and group notions of fairness to the question of how to define and implement merit-based decision making. Equal access theory has been overlooked in many interpretations of disparate impact's normative underpinnings. For example, Richard Primus offers two competing interpretations of disparate impact: reducing conscious or unconscious discrimination or increasing integration. He overlooks the equal access theory that most neatly matches the language, because it is really about advancing merit-based decision making and removing barriers that arbitrarily bias workplaces and higher educational opportunities in favor of particular groups.

The US and European conceptions of equal access seem to be moving in opposite directions. The US courts have been narrowing their definitions and approach to disparate impact, while the European Court of Human Rights has begun to "recognize the notion of indirect discrimination" (Besson, 2012; De Burca, 2012: p. 20).

Critiques of Equal Access Theory

Equal access theory has been called both over- and under-inclusive. It's potential for requiring radical restructuring of schools or workplaces prompts challenges based on the intrusiveness of such a theory into the autonomy of employers, admissions officers, and government officials. This criticism often proceeds from the view that courts should not engage in the process of institutional restructuring that they act illegitimately if they move beyond the role of dispute resolution and

compensation for discrete individual harms. The under-inclusiveness critique challenges the acceptance of merit or market criteria as a morally defensible basis for distinguishing between the opportunities of potential employees, college students, voters, etc. The weaker version of this critique, preferred by outcome theorists, argues that the continued pervasiveness of a caste system so infects the distribution of opportunities as to delegitimate a system of merit that produces racially identifiable results (Strauss, 1998). The stronger version of this critique challenges the moral legitimacy of differentiating access to social goods based on any arbitrarily distributed characteristics, including talents and motivation. "There is no more reason to permit the distribution of income and wealth to be settled by the distribution of natural assets than by historical and social fortune …. From a moral standpoint the two seem equally arbitrary" (Rawls, 1974: p. 74).

Judicial reluctance to embrace equal access in its robust form, focusing on discrete practices, has led some legal theorists and policy makers to question disparate impact as a viable theory for addressing persistent inequality (Bagenstos, 2006). For example, Michael Selmi concludes that disparate impact "has had a strikingly limited impact outside of the context of written employment tests and is, in fact, an extremely difficult theory on which to succeed." He contends that "whatever gains the disparate impact theory has produced likely could have been obtained through other means, particularly in large urban cities, and that the theory may have had the unintended effect of limiting our conception of intentional discrimination" (Selmi, 2006: p. 701). Many scholars, policy makers, and advocates are looking beyond the courts for arenas where barriers to mobility, access, and opportunity can be identified and challenged in a way that takes account of the mechanisms producing and reducing persistent inequality.

The differences in approach to equality summarized in this article recur in and help to explain deep fractures in judicial doctrine, legislative policy making, and public discourse about equality. Current debates often pose formal equality of treatment and equal outcome as the only two available conceptions of equality and force a choice between them. In the US, the complex dynamics of bias, along with the decreasing political and judicial viability of outcome and access theories of equality, have increased the attention to and importance of structural inequality, full participation, and unequal access theories of equality developed outside the courts. These theories are, however, the least normatively and empirically developed in the US. New governance approaches in Europe have opened up experimentation with positive theories of equality in the context of regional and supranational organizations, but these have yet to produce robust judicial enforcement or accountability systems. Emerging policy and scholarship emphasizes the decentering of courts as the primary elaborator of equality norms, the importance of nonjudicial venues for elaborating equality norms, and the emergence of equality strategies linked to broader normative goals. It remains to be seen whether courts and legal actors will respond dynamically to these new understandings of the dynamics and meaning of inequality and its relationship to law.

Abstract

The term *equality of opportunity* means different things to different scholars, policy makers, and popular audiences. This article explores the concept *equality of opportunity* with a focus on how it is used by students of stratification and social mobility, particularly in sociology. I suggest that a narrow definition of the concept *equality of opportunity* is the most fruitful one to adopt. Such a definition will lead students of inequality the opportunity to focus their analyses on inequality of results and conditions, rather than debating the conditions under which inequality can be legitimated. After all, equality of opportunity is partly determined by equality of conditions, whereas equality of results is much more visible and less elusive than equality of opportunity in its many interpretations.

The term *equality of opportunity* has philosophical, normative, political, ideological, and practical aspects, and it means different things to different scholars, policy makers, and popular audiences. At the philosophical normative end, the term is at the heart of a debate and discussion about just society. At the practical end, sociologists, and recently also economists, equate the term with social and economic mobility within a class or within other kinds of social structures. The two ends meet when students of social and economic mobility make inferences about *fairness* and *social justice* from studying social and economic mobility. There is neither an exclusive nor an agreed upon definition of the term social mobility. In fact, the term is elusive and difficult to operationalize and its critics argue that one of its main purposes is to mask and/or justify social and economic inequality of conditions. This article explores the term, or more accurately the concept, *equality of opportunity*, with a focus on how it is used by students of stratification and social mobility, particularly in sociology.

Equality of Opportunity and Stratification

Social stratification and mobility processes can be depicted as a race, with winners and losers obviously. Thus, social stratification and mobility processes are associated with inequality of results (of the race) and conditions. How one defines the concept *equality of opportunity* is important in assessing whether or not social inequality is fair and justifiable. A very wide array of definitions for the concept equality of opportunity exists in the literature, providing many – nearly all possible – justifications for the existence of inequality in society.

A thin definition of the concept *equality of opportunity* postulates that opportunities are equal as long as no overt discrimination on the grounds of race, ethnicity, gender, and the like prevents anyone from entering a race. This minimal definition is also known as formal equality of opportunity, and is concerned with equality of the access to available opportunity. Examples for the lack of equal access to opportunity used to be very common in the past. For example, for many years women did not have access to the political spheres and were denied access to higher education. This formal definition of the concept is apparent in the legislation.

Entering the race does not necessarily mean winning it, and thus the concept equality of opportunity can be extended to include also the rules governing the competition and how the winner is selected, that is, equality in the selection processes, once access is granted. At the formal level, an extension of the concept to include also selection processes would require, in the context of the labor market for example, the adaptation of race, age, gender, etc., blind procedures for job hiring and firing. Under such a policy, equality of opportunity does not necessarily mean that social background is not associated with the winners of the race. This is so simply because of the advantages and disadvantages that social background entails. Accordingly, a child of educated professional parents is better equipped to take advantage of the educational system than a child of uneducated working class parents. Defining equality of opportunity with reference to equal chances for access and advancement is akin to Sorokin's characterization of modern democratic societies, as societies in which "there are no judicial or religious obstacles to climbing or going down" (Sorokin, 1959: p. 153).

Equality of Opportunity and Mobility

A requirement that social background not be associated with the results of the race perhaps represents the broadest definition of the term equality of opportunity. This definition of the concept is very common in sociology, and also in economics, particularly among students of social stratification and mobility. Accordingly, intergenerational social and economic mobility is equated with equality of opportunity, such that the by now standard concept of *relative mobility* is taken as a measure of equality of opportunity.

Relative mobility can be explored by a transition matrix showing movements in, for example, a class hierarchy across generations. Relative rates are then treated as a set of (odds) ratios that measure the chances of having one origin rather than another for persons of one class relative to the comparable chances for persons in other classes. In the simplest case of

a 2 × 2 mobility table, the one odds ratio calculable would be given by the following equation:

$$\frac{f_{11}/f_{12}}{f_{21}/f_{22}}$$

where, f_{11} is the number of cases immobile in category 1, f_{12} the number mobile from category 1 origins to category 2 destinations, and so on. An odds ratio of 1 in this example implies complete statistical independence of the origin and the destination categories involved, or complete equality of opportunity. In mobility tables with more than two categories, it is possible, of course, to calculate more than one odds ratio, and other statistical techniques, such as log-linear analysis, are available to assess statistical independence.

Thus, if the odds of working class kids to end up later on in their lives in the upper class equals the odds of those born into the upper class to retain their privileged positions, then relative mobility – or *social fluidity* – is high and equality of opportunity exists within this society's class structure. This depiction of the term is best illustrated with references to the consequences of industrialization processes for stratification and mobility regimes. Accordingly, rapid economic development – a key element in the industrialization process – has resulted in the upgrading of the occupational structure of societies such that many new opportunities were created at the top of the occupational hierarchy. If these new opportunities are then taken equally by members of different social backgrounds, then equality of opportunity prevails. This interpretation equally applies to other social processes, most notably the educational attainment process. Here, the expansion of tertiary educational systems of most Western societies has created new opportunities at the top of the educational hierarchy. Equality of educational opportunity requires that these opportunities be shared by members of all social backgrounds equally.

The requirement that social background not be associated with the results of the competition represents a very wide definition of the term *equality of opportunity*, one that might require a compensatory mechanism for those underprivileged in society. A number of such mechanisms are discussed in the literature; the simplest one is a level playing field mechanism in which people are equalized before the race begins. Any inequality of results afterward is then justified. This mechanism, however, is at odds with normative ideas such as social justice and the notion of fairness. As Aristotle in his *Nicomachean Ethics* holds, if persons are not equal, they will not have nor be entitled to equal shares.

Equality of Opportunity and Competence

A more functional definition of the term equality of opportunity should therefore take into account people's competencies to realize the available opportunities (Marshall et al., 1997). That is, people with similar competencies should have equal chances to take on the available opportunities. In the educational attainment field this definition of the term equality of opportunity requires that members of various social backgrounds, but with similar ability, have equal chances for advancement in the educational hierarchy. In the social mobility field this definition normally requires that members of various social backgrounds, but with similar education, have equal access to the new opportunities that are created as a result of industrialization processes at the top of the occupational hierarchy.

In the sociological literature this idea is very clearly made by advocates of the so-called liberal thesis of industrialization advanced by American social scientists such as Talcott Parsons, Clark Kerr, and Daniel Bell. Accordingly, as well as changes in the structure of opportunities itself, industrialization alters the processes by which individuals are allocated to particular positions within the division of labor. Central to this argument is the shift away from *ascription* toward *achievement* as the principle criterion for social selection (Treiman, 1970). It is at this point that the theme of *meritocracy* comes to the fore. As Daniel Bell puts it: "by the logic of a meritocracy, these high-scoring individuals, no matter where they are in society, should be brought to the top in order to make the best use of their talent" (1974: p. 414). Thus, as merit comes to dominate social selection, the association between individuals' social origins and their destinations tends to weaken. As I have indicated earlier, when the association between social background and current social position is very weak, relative rates of mobility become equal and *equality of opportunity* is reached.

A major problem with this definition of the concept relates to the question: which competencies merit rewards? Put another way, can we justify unequal rewards on the basis of some heritable skills, IQ, or beauty? These questions can be linked to the issue of compensatory mechanisms earlier introduced, by focusing on those less privileged in society. Here we thus ask: the lack of which competencies should be compensated for?

The general consensus in the political philosophy literature is the idea that in striving for equality individuals should be held responsible for what happens to them (Roemer, 2002). That is, individuals should be held responsible for their preferences but not their resources (Dworkin, 1981). According to this line of reasoning, then, inequalities that arise from circumstances beyond our control should be considered illegitimate, while those that are the result of choice and preferences should be deemed legitimate (Phillips, 2004). But can we really distinguish between preferences and circumstances? Are not preferences also the results of one's position in the social hierarchy (circumstances)?

Examples for the intertwining of the two are numerous. For example, Hakim (2002) argues in her so-called preference theory that women select occupations that allow them to maintain the lifestyle they value. Most women, according to this argument, prefer a balanced work–family life and therefore select occupations that allow a better combination of the two roles. These 'preferences', however, do not necessarily reflect a choice free of constraint, as in the absence of public support many women are bound to adjust their occupational choices so that they meet their familial responsibilities. In a similar way, Breen and Goldthorpe (1997) explain the constancy of inequality in educational opportunity and, indeed, the existence of a stable class structure (cf Goldthorpe, 2000) in most modern societies by class-based educational choice. That is, members of the different social classes make different educational choices, which then result in the reproduction of the class structure. Hence, one can argue that ascriptive forces (circumstances) might often find ways of expressing

themselves as choice and preferences, as noted by Halsey (1977: pp. 173–186) in the context of social mobility in Britain.

Conclusion

To obviate these problems, I argue in favor of the narrowest possible definition of the concept *equality of opportunity*, one that requires the removal of all formal discrimination practices. Such a clear and lucid description of the term will lead students of inequality the opportunity to focus attention on studying inequality of results and conditions, rather than debating the conditions under which inequality can be legitimated. After all, equality of opportunity is partly determined by equality of conditions, while equality of results is much more visible and less elusive than equality of opportunity in its many interpretations.

Abstract

Equality is an enduring source of challenges for social practice, institutions, and analysis. Being no replica of identity in features of reality, it calls for normative judgment, hence its importance in moral and political thought. The close association of normative and descriptive elements typically brings about controversies about the right and relevant ways to secure the equal treatment of persons in their social life. Equality in status, equal opportunities, and equal rights are major concerns in this respect.

Equality is an object of inquiry in moral and political philosophy, as an ideal which pertains to the status of human beings as such (in a cosmopolitan perspective) and also to the treatment of individuals as citizens of a political entity and to the proceedings of social life. Although the equality ideal is usually vindicated, endorsed, or studied as a *de jure* requirement or an ideal to be rationally pursued, it must be considered in close association with the observation of empirical facts about the meaning attached to equal treatment in various cultural settings. The kind of equality which must be enforced so that reciprocity prevails is thus known to be highly dependent on the cultural characteristics of social life. While inequalities are plural, they jointly impact interpersonal relationships and social life, and they are under the common yoke of social institutions (Nadeau, 2007: chap. 2). The correlative social nature of equality aspirations suggests that equality is to be framed as a system of adequate social relationships (as in the variety of democratic equality defended by Anderson, 1999; see also Scheffler, 2003) rather than identified with patterns of distribution (or redistribution) of goods and bads. The complexity of moral and political thought about equality reflects the problems involved in the articulation of distributive operations and underlying concerns about equal treatment, equality in relationships, and equal dignity.

Equality as a Moral and Political Principle: The Variety of Philosophical Concerns about Equality

Ancient philosophers gave an expression to the ideal of the equality of all men, notwithstanding the contrast with their own political environment. In the Stoa, Zeno's *Republic* gave the example of a completely uniform *polis*, comprising only fellow-citizens and local residents, with only one way of life and order (Plutarch, *On the Fortune of Alexander*, 329). Ancient Greece provided analyses of equal treatment in social and political proceedings. In the Aristotelian treatment of monetary exchange, it is assumed that by means of convention, money makes different things tolerably commensurable and establishes the kind of equality that is necessary for exchange to take place (*Nicomachean Ethics*, V, 8). In the *Magna Moralia* (I, xxxiii, 28), it is explained that if a man is content to take less than his due, given that equality would have been a man's just due, injustice is only apparent; such a man is in fact exchanging part of his due for honor, praise, and the like. Inequality in friendship was also an object of scrutiny; those who are superior in wealth, for example, do not expect to love, but to be loved (they consider that they repay those who love them with the things in which they have a superiority); this is an object of ambition but being loved confers no benefit (*Magna Moralia*, II, xi, 34–40).

In Aristotle's *Nicomachean Ethics* (V, 2), the notion of equality plays an essential part in the definition of the just man; along with obeying the law, the just man is respectful of 'equality,' in contrast with the unjust man's taking more than his part of the good things, or trying to get less than his part of the bad things. In this classic treatment of justice, equality has the meaning of respecting a correct standard of behavior with respect to bad or good things, which makes it clear that philosophy should address the basic problem of setting up an interpersonal standard for the definition of such conduct. Aristotelian theory further developed the notion of proportionate equality, which made it possible to establish a direct connection with justice; in the *Magna Moralia*, it is thus considered proportionate that "one who has large possessions should pay a large amount in taxes, whilst he who possesses little pays little; and likewise that one who has toiled little also receives little. The ratio of the labours should equal the ratio of the receipts, and the ratios of labour to receipt equal one another" (*Magna Moralia*, I, xxxiii, 9, trad. G. Cyril Armstrong).

Equality had been studied in ancient times in connection with various moral subjects, ranging from having an equal temper in the face of adversity, or the importance of avoiding a degrading anger-inspired contest with an inferior (Seneca, *De Ira*, II, xxxiv, 1), to renouncing the conquest of advantage by violent means in favor of the kind of equality established by justice (Cicero, *De Officiis*, xix, 63). But equality as a moral ideal to be pursued through the fundamental rights and prerogatives attached to citizenship is by and large a modern notion. Equality among all human beings is a moral ideal which finds institutional expression, for example in the principles of political constitutions or international charters, or in officially proclaimed moral values (such as "Liberty, Equality, Fraternity" in republican France) or in fundamental legal arrangements. This can be illustrated by the emphasis of Condorcet on equality as the foundation of a republican constitution, which

helps preserve freedom and dignity, in accordance with nature, reason and justice ("*Exposition des principes et des motifs du plan de Constitution*," 1792, in *Œuvres*, vol. 12).

In some cases, the equality principle is taken to refer to the enjoyment of goods or property, or the command of revenue. But other politically and economically significant inequalities have a more procedural character, as they originate in the operations of social interaction: inequalities in information, freedom (Carter, 1999: chap. 3), recognized merit or effort, recognized talent or aptitude, level of independence, social influence, or friendly support. Kolm's theory of macro-justice sets out to give a firm grounding to the association between equal freedom and fairness in income redistribution, starting from a procedural view of equal social liberty for individuals who face restrictions on their choices (in particular, budget limits – see Kolm, 2005).

Significant Inequalities and the Ideal of Equality

In the political and social processes which convert empirical differences (which might partly originate in natural causes) into problematic political, social, or economic 'inequalities,' there is an important role for personal aspirations, goals, and values. Inequalities that matter are inequalities with respect to those human goals and values we should not ignore when we consider the sources of good or meaningful life in the human species. "Giving appropriate weight to interests for the sake of well-conceived equality might invite us not to give equal weight to all interests (however futile), in order to give more weight to those interests which deserve to be satisfied, or whose owners are entitled to have them satisfied" (D. Locke, 1981: p. 533). Such reasons support the centrality given, in ethical or political discourse, to a number of essential social dimensions of inequalities (which are usually not mutually independent from an empirical point of view): inequalities in property and income, educational inequality (unequal access to formal education, unequal opportunities in higher education, unequal quality of educational services), health-services inequality, job-market inequality, housing inequalities (access to housing facilities, quality of housing), inequality with respect to the availability of cultural goods and services, unequal quality of the environment, and so on. Due to the characteristics of particular societies in specific historical periods, such inequalities might have considerable overlap, leading to massive inequalities between social groups, communities, casts, or social classes.

In the eyes of most egalitarians, there is a deep connection between legal equality (the equal status granted by commonly recognized norms and institutions) and the achievement of a substantial form of equality, such as equal access to goods or services, or the command of equal revenue. Notwithstanding the practical difficulties and the fact that we are unlikely to achieve perfection in this respect, collective action should then be oriented toward the achievement of equal benefits for all from organized social life. Here, the means might have complicated connections with the ends. In many cases, public decision-making mechanisms will turn out to be necessary to make this kind of progress toward equality, but such mechanisms might prove deeply problematic from the point of view of equality itself. Indeed, they call for the institution of power differentials among persons, which can generate worrying inequalities.

Other, idiosyncratic practical difficulties should not be overlooked: inequalities are usually deeply rooted in social and economic life, in culture and traditions, in historical trends, and in geographical data. As a result, the effectiveness of collective action in the fight against those forms of inequality which are generally recognized as problematic is itself problematic, and an object of scrutiny. Furthermore, the practical obstacles might devaluate the currency of egalitarian speech, if the latter is excessively ambitious while we lack effective means of action. Concentration on specifically important dimensions of inequality, such as health care and education, is quite useful for pragmatic purposes. In addition to keeping the problems tractable, this strategy is usually rooted in needs which can be described as basic or essential. It is thus also amenable to plausible interpersonal comparisons and consensus.

Nevertheless, real egalitarians understandably want to go well beyond the development of widely accessible quality services in health care and education. Equality along more numerous dimensions of objective welfare can be vindicated with plausibility and, indeed, promoting equality in welfare lies at the heart of a variety of egalitarianism (see Arneson, 1989; Guibet Lafaye, 2006: chap. 2). With lesser intrinsic plausibility in predominantly free-market economies, equality in wealth or revenue is still a living ideal in the heart of hard-line egalitarians; for all its lack of plausibility when separately considered, this objective is influential as a limiting case when it comes to arguing for or against reforms that impact the prospects of greater or lesser material inequality, or inequality in access to goods and services generally speaking.

Concern for an encompassing view of equality might lead to the acceptance of inequality in treatment by state authorities, if such unequal treatment is framed as a way to remedy deep-seated social inequalities. This is the root of the 'affirmative action' strategies, which use differential opportunities to be appointed to significant positions in the public sector, or differential public support for educational opportunities, as tools to remedy pervasive and culturally inherited social prejudices and inequalities. Such concerns have led to short-term, transitory social strategies.

It must be acknowledged that we need go beyond the traditional precepts of equal treatment according to the law in order to secure significant results in terms of substantial equality, even though the enjoyment of an equal legal status with respect to basic rights, obligations, and liberties (irrespective of sex, religion, ethnic background, marital status, etc.) is obviously a problem in several countries nowadays. The resulting initiatives might appear problematic in the perspective of those doctrines which promote a purely process-based view of social justice (which is supposed to be rooted in equal respect for persons and their property, after the pattern described by Kolm, 2005; see also, for thorough analyses, Gamel and Lubrano, 2011). The problem is further connected with the frequent suspicion that redistributive or corrective social and economic action is, of necessity, dependent on particular value judgments, in such a way that individuals arbitrarily benefit or suffer from the opinions of others, in violation of

the moral equality of all human beings. This tension in the requirements of equality is, to a large extent, responsible for persistent conceptual and practical difficulties in the fight against inequalities. In order to effectively promote equality in the enjoyment of the goods or advantages gained through social life and common institutions, we must go beyond the sort of laws which formally institutionalize the protection of persons and their property, once a framework for the enforcement of a basic equal liberty for all is secured (let's say, in the spirit of John Rawls's first "principle of justice," formulated and explained in *A Theory of Justice*). To go beyond, we need laws that are political instruments in the fight about these inequalities which are found to be important by the rulers, with respect to the enjoyment of various advantages.

Many important issues in the field of inequality are mediated by individual rights. This raises specific problems because equality in terms of rights has its own importance, even though this form of equality is not automatically conducive to equality on all scores. As shown by J. Habermas (1992: chap. IX, sec. II), there is a dialectical link between right-based equal freedom and the unequal opportunities given to individuals to take advantage of their equal freedom (given the empirical social conditions that are partly the result of rights-exercising); this dialectic, Habermas argues, is central to the development of law in the contemporary world. Historically, the compatibility of first-generation (eighteenth-century) fundamental human rights with worrying social and economic inequalities (such as educational or health-related inequalities in particular) has been a major reason to try to develop a more encompassing concept of human rights, in order to take the social and economic dimensions of life into account.

Unemployment, no less than unrewarding activities, threatens the equal ability of citizens to value the kind of life they can choose to live according to their own conception of the good (Guillarme, 1999: chap. 5); other challenges are posed by segregated social roles and by the kind of identity-threatening social disrespect that is given prominence in Honneth (1992), which motivate effort to integrate egalitarian redistributive views and recognition concerns (Phillips, 1999; Fraser and Honneth, 2003). All in all, the connection between workplace activity (or redundancy), social respect, and social rights stands as a major challenge for equality in our times, in the face of evolving, often problematic forms of workplace and housing inclusion or exclusion. Promoting equality in individual functionings and capabilities (as classically defined by Sen, 1992) is a plausible strategy for addressing and interrelating a number of core insights and concerns in the field, even though the anthropological and sociological underpinnings of the capabilities approach are quite specific.

Natural Equality and the Social Treatment of Individuals

Equality is an ideal with respect to both representations of the nature of human persons and conceptions about the fair treatment of persons by other persons as well as collective agents. It is usually hypothesized that the second perspective is determined by the first one. In particular, holding the view that human beings are equal beings is widely thought to be a sufficient condition for holding that human beings should be treated equally. At the level of fundamental moral dispositions, this is convincing indeed: equality of status implies that, when human beings are simply considered as human beings, there is no reason to believe that they should be treated unequally in their mutual relationships, and unequal claims would be unjustified in the first place.

Such ideas have had a profound influence in the history of mankind. In particular, the gradual realization that men and women are equal, as well as human beings with different cultural background and skin colors, has been a crucial source of inspiration for progress in the equal treatment of men and women, and similarly in the case of equal treatment for people with different cultural backgrounds (consequences must then be drawn for the colonial experience) and in the case of equal treatment for people with different skin colors (with consequences for the abolition of slavery and apartheid). In detailed social, administrative, or political problems, the basic claims associated with the fundamental status of human being are not usually considered in a direct manner. Even when equal treatment is an option, it is generally not automatically considered the best one, owing to the association of the relevant individual claims with the particulars of joint work and mutual advantage, personal capacities and the public goods, individual talents and overall economic efficiency, and the combination of personal traits and social life.

Most of the claims about justice are compatible with serious cases of inequality which can often plausibly be interpreted as examples of the unequal treatment of individuals in (or by) society. More often than not, such inequalities are actually required by the selected views about justice. This raises a natural question: if 'justice' requires a departure from strict equality, how can it count as an expression of justice in the first place? Does it not stand to be criticized on account of the violation of equality? A standard answer consists in saying that ideals of justice are always ideals of equality or equal treatment in definite respects which are considered central or most important for the questions at hand; this might involve inequality in other respects, in such a way that fairness or equity is safe. This answer accounts for the diversity in opinions or doctrines about justice when it comes to deriving their implications in terms of inequality or equality (Sen, 1992).

For example, theories of justice which focus on equality in the enjoyment of personal rights (such as property rights) are, in principle, compatible with wide inequalities in terms of material welfare or financial resources. As a matter of fact, respect for free, consent-based interactions between adult persons normally commits one to accept unequal outcomes, unless these are being actively corrected so that they conform to equality ideals in all essential respects. If the latter kind of correction is taken to be inappropriate, then one should be prepared to welcome inequality. Other theories, which articulate ideals of equal treatment in connection with welfare or resources, might accommodate unequal protection of persons and goods, or the denial of due process in judicial activity. For example, this awkward property might originate in the fact that progress toward economic equality is taken to involve revolutionary episodes and class conflict.

To be sure, inequality raises problems of identification: how can we check that two situations are 'equal'? Which criteria can we use to assess the presence of inequality (the kind of inequality we are interested in) in particular cases? Furthermore, given a general description of the kind of inequality that is of interest, judgment in particular cases presupposes the availability of criteria that enable us to process the pieces of information that are included in the data. Normatively speaking, the main problems of inequality have to do with the connection between inequality and social justice (or fairness), as emphasized in the socialist and liberal political traditions. This accounts for the usual negative value judgment about inequality, even though inequality discourse is seemingly descriptive. As noted by Hilary Putnam (2002), description and value judgments are intimately connected in the ways to address inequalities. Consider the interest we take in the interpretation of empirical measures or descriptions of social and economic inequalities in given societies; this kind of interpretation is deeply influenced by the selection of morally or politically relevant aspects of the distribution and by the choice of the underlying characteristics that are the object of description or measurement. The interplay of norm-based value judgments and empirical statements is remarkable here, as it occasionally conditions the recognition of empirical knowledge as relevant, faithful to its purpose, or even adequate. Indeed, a failure to develop morally or politically relevant measures of inequality – measures that enable one to assess the kind of inequality that should be attenuated or suppressed – is likely to be interpreted as a failure to describe (or measure) inequality in the first place.

To be sure, active fight against inequality by political or legal means is not always appraised positively (e.g., it was repeatedly and notoriously criticized by Friedrich von Hayek). In addition, divisions occur about the seriousness or the relevance of inequalities. For example, in the long-standing controversies in contemporary Greece about differentiated tax rules, there is no homogeneity of judgment about the problematic nature of the Church's advantages; for some, this amounts to a serious departure from the standard of equality; for others, this is an inconsequential form of differentiated treatment, or an inequality that should be regarded as negligible if we focus on the associated advantages, for example, with respect to the preservation of the nation's cultural heritage. Actively fighting inequality is sometimes criticized on account of the alleged conflict with everyone's free access to the benefits of one's own effort – an argument which is regularly defeated in various contexts by appealing to the fact of widespread social interdependence in education, in the division of labor, and in the social background of fruitful activity.

The kind of equality which is of interest for normative social science and for moral and political philosophy seems to be amenable to description as a variety of equal treatment in an organized social process. Normative discourse about inequality is typically not a discourse about natural differences (or differences with a very strong natural grounding), such as differences in physical strength, quick-mindedness, and so forth, even though the common descriptions of such interpersonal differences are often based on comparisons which provide a common ground with inequality speech: people have a 'more or less' robust constitution, they are 'more or less' quick-minded, and so on. When differentiations of this kind are taken into account, the underlying questions have to do with the neutralization of their influence in the processes of social life, possibly by means of compensation schemes. Relevant questions might also have to do with the collective use of natural assets. How are we collectively to benefit – in an efficient and fair way – from a distribution of natural assets? A typical, more detailed question is, for example: how should we organize social institutions so that the unequal distribution of individual dispositions is put to use in a satisfying manner (both efficient and equitable), given our differences in needs?

Equality, Democracy, and Contractarian Methodology

Human beings are not naturally unequal between themselves to the extent they are in their social life. Moreover, the development of social inequalities might make it difficult for some individuals to give their consent to social arrangements that threaten comparatively advantageous positions in these inequalities, especially if their own situation is less favorable in such alternative patterns of the social order. From a rationalist perspective, however, a moral judgment about the social order should *a priori* commit ourselves neither to the defense of an antecedent, inherited order, nor to the *defense* of personal interests in a special way. On the contrary, it should equip us with a more detached perspective – the kind of perspective needed when we raise questions about the justice or fairness of social institutions. These are some of the reasons which give credibility to John Rawls's statement according to which "despite the fact that the contract doctrine seems at first to be a somewhat special conception, particularly in its treatment of inequalities, it may still express the principles of justice which stand in the background and control the weights expressed in our everyday judgments" (Rawls, 1967: *Collected Papers*, p. 153).

Contractarianism (the family of moral, ethical, and economic doctrines which place emphasis on possible unanimous agreements on basic social arrangements after the pattern of a 'social contract' in order to evaluate, justify, or criticize such arrangements) invites us to judge social inequalities by the standards that would be selected by free people in a state of equality, as proposed by the core models of social contract theories. Philosophical analysis should equip us with a benchmark 'equal' situation which can offer a basis for normative reasoning; such is the general meaning of an original position's design in contractarian theory. It should be observed, though, that the theoretical functions of this design are plural. Following Hobbes and Locke, contractarian theorists refer to a virtual original position which is a state of (at least approximate) equality. This accounts for the defects or positive reasons why people should be content with institutional arrangements of some sort (e.g., the existence of sovereign authority, as classically justified by Hobbes in his *Leviathan* in the successive 1651 and 1668 versions, or the existence of judicial arbitration, as explained in Locke's *Two Treatises of Government*, 1689). Rational choice and self-interest are then instrumental in identifying the reasons why the described state should be viewed as imperfect and transient.

Rousseau's assumptions about the initial equality of men in their natural condition also perform this kind of reason-providing function. Both in the *Social Contract* (1762) and in the sketch of a correct collective arrangement in the second *Discourse (Discours sur l'origine et les fondements de l'inégalité parmi les hommes, 1755)*, the natural equality of men provides a standard to appreciate both the poor condition of men as a result of the progress of civilized life (which involves property, power and wealth differentials, and so on), and the kind of freedom that is regained by a true social contract, given the widespread interdependence which is a result of social life. But the partly narrative, partly predictive social theory which is developed in the second *Discourse* enables contractarian theory to play the additional role of explaining how poorly reflective and badly informed unanimous choices, starting from an intermediate state of inequality among men, might account for the social enforcement of unequal institutions and, subsequently, massive inequality in modern societies.

In spite of the egalitarian features of 'states of nature' or original positions, the conclusion of a contractarian argument is not necessarily egalitarian. At the procedural level, however, equality is required. The ideal of equality is expressed through the methodological requirements which make it possible to reach conclusions in an impartial way. In Kant's use of the social contract as a criterion of justice, the condition of a possible universal assent of all citizens to public action yields an impartial test for revealing the unjust nature of given acts of government. Along different routes, this line of inquiry was pursued in Harsanyi (1953, 1955), who proposed a renewal of contractarian methodology (starting from rational-choice premises and leading to neo-utilitarian statements), and in Rawls's *Theory of Justice* (1971).

The conclusions of Rawls's theory of social justice are compatible with marked inequalities in the panels of 'primary goods,' that is to say, goods which are involved in all avenues of life, no matter the personal choices or conceptions of the good life. Such goods are secured to individuals by the basic features of a social 'structure' and their allocation is the proper object of analysis for the proposed economic and political justice. The ideal of equality is expressed through the structure of the overall treatment of justice, which culminates in the statement of the two 'principles of justice' with their companion priority rules. The equal allocation of a maximally defined set of basic individual freedoms is firmly granted by the first principle. 'Fair equality of opportunity' in the Rawlsian sense states that, given equal talent and similar ambition, the prospects of reaching social positions (with their associated prerogatives and advantages) are the same, and the positions are open for all in the first place. Beyond this requirement, the second principle, which makes use of the 'maximin' logic (an ordering principle which invites us to look first at the situation of the worst off when ranking possible distributive patterns, then at the situation of those who occupy the other positions), further secures that all individuals are, in some sense, equally treated as ends in themselves: each of them should be able to view society as best organized for his or her own endowment in all-purpose primary goods.

Following Rawls (1971), equality is deeply connected with the procedural analysis of justice. The model of a choice under a 'veil of ignorance' in an 'original position' is rooted in a quest for equality and impartiality in the deepest layer of the theory, although is leads to conclusions which are questionable from an egalitarian point of view. ('Veil of ignorance' is an argumentative strategy which focuses on a thought experiment through which a number of empirical (social and personal) characteristics of individuals are put aside, so that their influence on the outcome of choice problems is nullified.) Following the proposed methodology, all members of society are supposed to have a say in the collective articulation of principles of justice for the regulation of the basic structure of their society. But the kind of judgment which must be reached is moral in character; it should help us answer questions about the justice of social arrangements, and these cannot be reduced to strategic or tactical political questions, nor to economic efficiency matters. In the continuity of Locke, Rousseau, and Kant, Rawls develops a vision of equality according to which all human beings should be treated equally in connection with the basic social structure of society, and this finds an expression in a choice under a 'veil of ignorance,' which blocks the influence of contingent factors such as age, sex, and social origin. This methodology nullifies the influence of contingent factors which might impair impartiality in the choice of principles for the whole of society.

Contractarian methodology yields benchmarks for assessing the legitimacy of power, and the equality assumptions which are typical of this methodology are congenial to the moral underpinnings of democratic theory. This convergence allows adequate contractarian justifications of power to be recognized as valuable contributions to the legitimacy of democratic power. From a practical point of view, however, investing specific people with special powers or prerogatives is a major source of inequality. Obedience to authority, even when its justification is clearly associated with equality-based normative reasoning and judgments, is a source of concern with respect to equality.

Controversies about Possibly Legitimate Sources of Inequality

Neutralizing power asymmetries among individuals, even legitimate inequalities, is central to the quest for proximity that is associated with contemporary methods of participative deliberation. Nevertheless, participatory democracy on a local scale draws attention to a less-than-general concept of shared will. The resulting dialectical tension with what is referred to as the common good or the general will at the level of the political community at large is in turn a source of worries for the equality of citizens. If obedience to political authority is to be understood as obeying to one's own prescribed law after the pattern of Rousseau's ideal social contract, a key requirement of the kind of equality which is being pursued in rule-making is that we only refer to one kind of united wills. Giving weight to separate interests, even in the form of shared interests for the concerned parties, might be problematic for the effective pursuit of equality among citizens. There is a philosophical problem in this respect, because inclusion of various groups of concerned persons in political debates, including local groups of stakeholders,

might turn out to be crucial to giving each individual a voice which can be heard in an effective way, thus promoting equality in the form of a remedy to power asymmetries; it might also be crucial to helping individuals in the elaboration of their own values or interests in a reflective way, thus giving moral significance to equal involvement in debates and decision-making.

Acting out of respect for equality might be compatible with a differentiated treatment of persons whenever personal effort or contribution is itself differentiated. Otherwise – so the argument goes – effort or personal involvement (or merit) would not receive equal consideration; think of the shareholder model of just retribution, classically used by Leibniz (1702), for the purpose of clarifying the common notion of justice. For example, lack of punishment for offenders would not amount to a contribution to equal treatment but should rather be viewed as a violation of the requirement of equality.

In contemporary philosophy, this line of reasoning is still influential in the doctrines which identify a difference between tolerable inequalities and other inequalities, which should come to an end. The difference created by the display of personal merit offers a popular criterion for the differentiation between the two kinds of inequalities. People should not be held responsible for the differences between them that testify to the role of causes which are beyond their full control, such as the genetically determined features of their bodily constitution, or the early stages of the education they received, and even their talent and (dis)abilities. As they do not control such things, they should not be held responsible for their consequences in their own life; this has been described as a development of the idea of equality of opportunity, which is central to liberal and democratic thought (Freeman, 2007: p. 111). This opens the way to the critical reflection on collective attitudes toward social and economic inequalities, if we insist that these attitudes should testify to the commitment to suppress the contingent influence of accidental causes, thus enabling us to realize a significant kind of equal treatment in our social life (Dworkin, 1981; Cohen, 1989; Arneson, 2001; Fleurbaey, 2008; Spitz, 2008).

At the same time, this raises questions about the connection between equality and a fair treatment of individuals in their social life. According to some, the kind of respect for individuals that should be displayed by society must have its departure point in the serious consideration of individuals as they are. Their nature is not just the nature of rational persons: they are also constituted as individuals by the contingencies of life, through their own particular experience as living beings. Therefore there would be nothing partial or unfair about letting them being treated in a differentiated manner due to their contrasted ability to benefit from their own personal features (gifts or handicaps, social origin, age, etc.) and social involvement (educational connections, friendships, family links, etc.). On the contrary, if fairness is supposed to commit us to nullify the impact of contingent factors which are beyond the control of individuals, active intervention is required by the imperative of equal treatment. Along the same lines, it can even be argued that fairness ideals commit us to the active support of 'fair' inequalities (those economic inequalities which result from contrasted workplace effort, educational initiative, or active social involvement in collectively useful directions).

Equilibrium: History of the Concept

Till Düppe, Université du Québec à Montréal (UQAM), Montréal, QC, Canada

Abstract

Equilibrium analysis largely identifies the scope of theory in today's economic research. This prominent place has several historical origins. Before the notion was first used, equilibrium arguments were already applied in early modern writings on trade. Not before the late eighteenth century, the concept became part of the vocabulary of political economists. It was used as an analogical and, moreover, normative concept referring to the natural order of the economy. At the end of the nineteenth century, the concept gained analytical meaning, specifically because of the difference between static and dynamic equilibrium. Between the 1940s and the 1960s, the concept grew into a metatheoretical notion as the corner stone of axiomatic general equilibrium analysis, which in turn would become the bedrock of current mathematical modeling. Equally in game theory, the concept is the main analytical tool, though not limited to competitive interactions in markets. It allows formalizing institutional environments and strategic interaction on an individual and group level. In nearly all macroeconomic modeling, general equilibrium theory continues to be the prevailing reference point.

Equilibrium analysis largely identifies the scope of theory in today's economic research. Since there are many economic theories, the concept refers only vaguely to specific beliefs or ideas about economic reality. Instead, it provides cohesion to the economic way of modeling in the social sciences, and thus corresponds with a 'style of reasoning' typical for the discipline of economics (Hacking, 1992).

The prominent place that the concept occupies in economics today has several origins. Before the notion was first used, equilibrium arguments were already applied in early modern writings on trade. Not before the late eighteenth century, the concept became part of the vocabulary of political economists. It was used as an analogical and, moreover, normative concept referring to the natural order of the economy. At the end of the nineteenth century, the concept gained analytical meaning, specifically because of the difference between static and dynamic equilibrium. Between the 1940s and the 1960s, the concept grew into a metatheoretical notion as the corner stone of axiomatic general equilibrium analysis, which in turn would become the bedrock of current mathematical modeling. Equally in game theory, the concept is the main analytical tool, though not limited to competitive interactions in markets. It allows formalizing institutional environments and strategic interaction on an individual and group level. In nearly all macroeconomic modeling, general equilibrium theory continues to be the prevailing reference point despite its limited use for empirical analysis.

Since the concept functioned differently at each point of time, one better views its history as a sequence of transformations of different, not necessarily reducible scientific cultures in economics. The history of the concept is nevertheless significant insofar as in current economic research as well as in economic policy more recent and at the same time older meanings of the concept are used interchangeably.

Early Forms of Equilibrium Arguments

Before the concept was used explicitly, equilibrium arguments can be traced back to early modern economic writings of the seventeenth century. Since the form of argument is fairly simple, one could without doubt find yet earlier uses. The discursive situation from which these arguments emerged was early modern writings on trade, mostly pamphlets written in the context of the council of trade. Equilibrium arguments provided a rationale for fixing quantitative measures such as price limits, tax levels, import quotas, etc. Previous arguments that used the Aristotelian and medieval concept of the just price, lacked such a rationale. To give but one example: William Petty, when speaking of the limit between a reasonable rate of interest and illegitimate usury, argued that the interest rate should be as high as the rent of land, for *if not*, financial investment would soon outweigh agricultural production (Petty, 1899: 48). Similar arguments regarding excess supply and demand can be found in the writings of Sir Dudley North or John Locke (Letwin, 1963: 198; Tieben, 2012). Equilibrium arguments are a form of hypothetical reasoning that replaces normative arguments about economic measures such as price ceilings or tax levels. They require a notion of interdependence of two or more economic variables, the change of one of which induces the change of the other and vice versa. The causal mechanism of this endogenous change, however, must not be fully specified. Hence, equilibrium arguments were present in economic writings before the concept was explicitly used in terms of a specific ontology of the nature of economic order.

Not all arguments involving interdependence, however, are equilibrium arguments, as, for example, Francoise Quesnay's *tableau économique* that traces the causal effects of growth in one sector, agriculture, onto all others (Quesnay, 1766). Even though equilibrium arguments do not require full causal explanations, they equally should be kept apart from identity arguments that were also frequently used in seventeenth- and eighteenth-century economic writings. The so-called Say's law might be the best-known example that states that (aggregate) supply and demand cannot diverge because they are mutually determined. Identities cannot be unequal and thus serve as principles from which equilibrium arguments can be constructed. An example of a very influential early equilibrium argument that shows the difference between identity,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03081-6

equilibrium, and causality is Hume's so-called price specie flow (1752: 82ff.). Hume argued that a trade surplus cannot be maintained in the long run, as mercantilist writers assumed, because the inflow of gold would increase domestic prices that in turn leads to less export and more import until the balance of payments is restored. The identity of price level and money supply is assumed, the equilibrium argument is hypothetical, and the actual causal mechanism of the economic agents who respond to price differentials is unspecified.

Analogical Uses of the Concept of Equilibrium

In order to possess explanatory value, equilibrium arguments must include an ontological dimension beyond hypothetical reasoning: the nature of the causal mechanism that brings about endogenous change must be specified. Classical political economists established this explanatory value of the concept by means of the analogy between economic and natural order. Elements of the market economy, say, different parties of trade, relate to one another like elements in other domains where the belief in an ordered system was already established. This analogical usage of the term was decisive for establishing the belief in an orderly sphere of the economy as an object of systematic inquiry.

The very first appearance of the concept in the history of social thought is difficult to identify because the concept has been already established in other than social writings where it described mechanical movements, interstellar forces, anatomic proportions, which often had, typical for eighteenth-century authors, also creationist connotations. The French writer Pierre de Boisguilbert (1646–1714), to whom Spiegel assigns first usage, used the term when comparing economic and divine order (Spiegel, 1991: 614). For him, equilibrium refers to a state of opulence. He also used the analogy with mechanics according to the original Latin root of the word – 'equal balance' – in order to explain the price mechanism:

> It is like a balance suspended in equilibrium because the weight is equal in each of the two scales. A hundred pounds of any material whatever cannot receive an increase of even two pounds in one of the two scales without destroying the equilibrium. This, then, is precisely what takes place with regard to the price of grain. An increase or a diminution of twenty sacks at the market or staple house above or below the ordinary supply of five hundred sacks offered every week, destroys the balance, and makes it fall immediately on one side.
>
> Boisguilbert, 1966[1707]: 859

After such occasional uses in the early eighteenth century, the concept became part of the vocabulary of political economists during the Scottish enlightenment of the late eighteenth century. While the concept was also used by James Steuart in 1769 (see Milgate, 2008), the *locus classicus* of the analogical concept of equilibrium is Adam Smith when speaking of the 'gravitational force' exerted by the natural price (Smith, 1961 [1776]: 60ff.). The natural price, according to Smith, reflects (long-run) production costs while the market price varies according to short-term deviations of demand or supply. These deviations are 'forced' back to the natural price by means of rivalry between either consumers or producers.

> The natural price … is, as it were, the central price, to which the prices of all commodities are continually gravitating. Different accidents may sometimes keep them suspended a good deal above it, and sometimes force them down even somewhat below it. But whatever may be the obstacles which hinder them from settling in this center of repose and continuance, they are constantly tending towards it.
>
> Smith, 1961[1776]: 65

'Gravitational forces' of the market refer to the effects of changes of demand (that is degrees of wants for conveniences and of needs for necessities) given the limitations of production (that are determined by local natural resources, technology, capital maintenance, and labor costs). Such are the economic 'forces' to be brought into balance by the price mechanism that imposes costs and benefits on decisions of producers and consumers. Being in rivalry with one another, they react to price differentials.

Next to physical or celestial analogies, anatomic analogies are also frequently used in economic writings of the eighteenth century. After William Harvey's discovery of blood circulation, economic writers commonly described trade in anatomical terms. Money flows through the economy like blood through veins. Thomas Hobbes was one of the first, John Pollexfen, Jacob Vanderlint, Philip Cantillon, and others followed in calling the public treasure the heart of the state and money its blood that makes its organs reach out to other states – e.g., by paying armies (see Walter, 2011: 40–47). This anatomical analogy held both ways to the extent that the notion of the economy was habitually used in medical treatises when one spoke of the economy of the body and its natural equilibrium. Diseases were defined in terms of the divergence from this equilibrium, such that equilibrium took on older meanings of moderation and lack of excess.

These analogical uses helped establishing the field of political economy as an inquiry into an orderly object of study. It established the belief that "certain systematic or persistent forces, regular in their operation, are at work in the economic system," which is the most general feature of the concept of equilibrium according to Milgate (2008). The analogy was put forward against the belief that economic phenomena are manifestations of the blind forces of power and thus are not intelligible or predictable in systematic terms. This contrast with the concept of power will be present throughout further transformations of the concept.

The analogical use also established the very prominent normative meaning of a state of harmony of interests in a free-market society. Smith's natural price implied harmony between the three classes of labor, capitalists, and landowners. His analogy nourished the idea that once left alone, the economy spontaneously forms its inner order such that market interventions seeking power over the economy disturb this natural order, and thus the harmony of interests. Free competition allows the natural forces of the economy to bring about an orderly, harmonious, and thus desirable state of the economy. Even though Smith also propagated many government responsibilities, he thought of free trade as the system of natural liberty: complete resource mobility and free entry and exit in all markets. His system of natural liberty referred to institutions that induce rivalry between economic agents that are necessary for the 'gravitational forces' of the market to be at work (Smith, 1961[1776]: 687).

Classical political economists hardly ever felt obliged to spell out the analogy of the concept of equilibrium to such extent that the nature of economic forces could be empirically tested or even analytically determined. In fact, if used solely in an analogical fashion without the hypothetical reasoning referred to in the previous section, classical political economists added little to the normative arguments of natural law philosophers. In turn, the normative meaning of the concept of equilibrium, until today, has never been fully argued for without analogical elements (see Düppe, 2011).

The fact that the equilibrium concept rather imported familiarity into economic discourse than provided explanations of the market mechanism was still true when late-nineteenth century neoclassical writers used the concept, such as William Stanley Jevons. His analogy was that of the equilibrium of prices and that of a pendulum:

> We can no more know nor measure gravity in its own nature than we can measure a feeling; but, just as we measure gravity by its effects in the motion of a pendulum, so we may estimate the equality or inequality of feelings by the decisions of the human mind. The will is our pendulum, and its oscillations are minutely registered in the price lists of the markets.
>
> Jevons, 1970[1871]: 11

Already before Jevons, however, notably with John Stuart Mill, skepticism regarding the empirical merits of the analogy emerged. Mill emphasized that economic laws hold only under very restrictive conditions that can, in contrast to natural laws, never be fully observed in reality (because of the absence of controlled experiments). Due to noneconomic interfering causes only tendencies toward states of equilibrium can be observed. The classical laws of the market are true only 'in the abstract,' that is, "they are only true under certain suppositions, in which none but general causes – causes common to the whole class of cases under consideration – are taken into account" (Mill, 1844: 144–145). In this fashion, Mill opened the way to the analytical notion of the concept of equilibrium, specifically by pointing to the significant fact that initial conditions of the equilibrium, in the concrete, may change 'on the way,' and that hence the static idea of a market equilibrium must be supplemented with a theory of dynamic change (Mill, 1848: 421ff.). Thus, Mill introduced a distinction that was to remain present in all equilibrium analysis: the difference between static and dynamic equilibrium analysis.

The Analytical Concept of Equilibrium

It was only in the last decades of the nineteenth century, specifically after the work of Léon Walras (1834–1910) that equilibrium became a theoretical concept that could be analyzed in its own terms without reference to other domains of research. Decisive was the idea of representing the economy as a system of equations in Walras's *Elements of Pure Economics* (2003[1874]). Similar to nonconceptual uses of the word when one speaks of a balance of payment to be in equilibrium, equilibrium as the solution of a system of equations refers to the state of market clearance where aggregate demand is equal to aggregate supply. Equations are separately defined for demand and supply in all goods and factor markets that each depend on the price of the good of this market and all other goods and factor prices being either complements or substitutes. Equilibrium refers to a set of prices that solves all equations simultaneously.

Even if Walras's inspiration was a textbook by Louis Poinsot on the mechanical equilibrium of a solar system (Ingrao and Israel, 1990: 88), and even if later in his life he defended his approach by an analogy between economic and mechanical concepts (scarcity and utility relate to one another like force and energy, see Mirowski and Cook, 1990), Walras did not believe that economic and natural phenomena are reducible to one another. He moved beyond analogical reasoning insofar he put emphasis on the common mathematical structure while recognizing the ontological differences between these domains. Accordingly, Walras distinguished, similar to Mill, between pure, applied, and social economics, while only in the context of pure economics, an equilibrium could be properly defined. Little ontological commitment was transmitted by Walras's analytical concept of equilibrium. Instead, he opened the door to mathematical modeling, specifically to linear algebra.

The aim of Walras's system was the representation of the interdependence of all markets. Agents all over the economy that appear to be unrelated are connected by the price system. Equilibrium thus contrasts to fragmentation of the economy, in which case one could say very little about a market economy as a whole. This interest in capturing interdependence is often contrasted with Alfred Marshall's (1920[1890]) analysis of markets: the latter representing partial, the former general, equilibrium theory. Marshall sought to understand the mechanism of single markets, *ceteris paribus* all effects on other markets. What allowed Marshall to do so was a distinction between causal factors being relevant for different periods of time (1890: Book V). He distinguished, first, the market period in which goods had been already produced, supply is thus fixed, such that prices depend solely on demand; second, the short-run period in which production can be expanded altering some production factors, but not all due to prime costs; third, in the long-run all production technologies can change, while demand is stable. Consequently, as to whether or not one considers being in equilibrium depends on the period of time one considers. Such was Marshall's take on the problem of dynamics – the problem that the endogenous changes induced by a disequilibrium changes the initial conditions of equilibrium, such as income and technology.

Walras's instead, in his framework of general equilibrium analysis, bypassed the problem of dynamic change by speaking of an 'auctioneer' who identifies the set of equilibrium prices by 'crying out' random prices before any transaction is taken (Jaffe, 1967). This comparison with the stock market was clearly not an identification of the causes that bring prices into equilibrium, as Marshall would have it, but the possibility of an algorithm that describes the change of prices within his system of equations. The Walrasian auctioneer, as an analytical creation, allowed for equilibrium theory to develop theoretical problems of its own prior to its applications. When Walras considered actual price changes, he drew back and referred once again to a natural analogy, a lake agitated by the wind, saying that initial conditions are in continuous change due to the changes caused by a disequilibrium (Walras, 2003[1874]: 380).

Nature, no longer a source of the belief in an orderly domain, changes faster than the market can adapt.

Next to the static and dynamic equilibrium, another analytical difference that became prominent from contrasting Marshall and Walras was that of aggregation and disaggregation: Can the conditions of market equilibrium be traced down to the individual level? Marshall assumed what is nowadays called a representative agent such that even the marginal utility of income was supposed to be the same across all income levels. Walras equally started from aggregate market demand and supply functions, even if his set of equations could in principle be spelled out in terms of disaggregated individual functions – or so he and other neoclassical economists assumed for a long time until the opposite was proven in the 1970s, as we see below.

In the hands of Walras, a significant transformation of the concept took place regarding its normative welfare dimension. Perfect competition for Walras means that prices are independent of demand and supply functions, i.e., they are 'given' to economic agents. Gone was the close link between rivalry and free-market institutions such that it was no longer obvious in which institutional context equilibrium theory would apply. This was indeed not the task of pure economics according to Walras. As a result, the normative meaning of the concept of equilibrium was no longer the harmony of interests and the natural system of liberty, but the absence of waste and the efficient use of resources as the formal implication of market clearance. Neoclassical welfare economics is in fact less an argument for specific economic institutions or policies, but the development of criteria according to which various institutions and policies, interventionist or not, could be evaluated.

Equilibrium and Time

The distinction between static and dynamic equilibrium remained the driving force of innovations involving the concept of equilibrium in the first half of the twentieth century. An important complication of the problem of dynamics was, rather than income effects, the uncertainty of long-term investment decisions that has short-term effects. An important consequence of this uncertainty is that there is no reason to trust that profit rates are unique across all markets. And so the concept of equilibrium was in the background of a range of institutional questions regarding monetary and business cycles theories that were put forth by Austrian economists. Böhm-Bawerk, for example, spoke of an intertemporal equilibrium considering both long-term and short-term plans simultaneously in a trade off between current and future consumption (Böhm-Bawerk, 1959[1899]). In further course, including uncertainty in equilibrium analysis, most notably after John Maynard Keynes, generated a whole bunch of new analytical problems that were largely unknown to political economists, and, in further course, only vaguely linked with traditional price theory. What came to be labeled as macroeconomics gained shape in a certain distance to equilibrium analysis.

It was not before John Hicks (1904–89), in response to the work of Lindahl and Hayek, and in trying to reconcile Keynesian and Walrasian theories, that a different interpretation of equilibrium was introduced to solve problems of time and uncertainty: the temporary equilibrium (Hicks, 1939). Hicks specified the process by which an equilibrium comes about in *sequential* terms. He spoke of a market period called a 'week' defined as the period in-between transactions that allow for carrying out production plans. Equilibrium was thus no longer defined in terms of long-run forces and short-run disturbances. Adaptations and decisions were sequentially separated. Insofar as at each transaction day a new equilibrium is achieved Hicks bypassed problems of the coordination of expectations. At each period of time there are different market clearing prices.

Also the normative dimension of the equilibrium concept was heavily influenced by these new problems of time, as is evident in Oskar Lange's idea of market socialism (1938). Lange reinterpreted Walras's general equilibrium theory as an economic theory of socialism with public ownership of production factors. The central planning bureau sets prices like a Walrasian auctioneer, observes excess demand and supply via inventory data, and reaches equilibrium by adapting factor prices accordingly. Against this use of equilibrium analysis, Friedrich Hayek put forth a concept of competition that is opposed to any notion of equilibrium: competitive institutions are preferable as they result in the most adaptive utilization of local knowledge. It is only in a continuously changing environment, that is, in disequilibrium, that the price mechanism shows to be superior to a bureaucratic system (Hayek, 1945).

Axiomatic Equilibrium Analysis

Between the 1940s and the 1960s the concept of equilibrium became the central means by which mathematical modeling was advanced, and conceptual and other literary economic theory were replaced. The concept of equilibrium became the symbol of the culture of economics being different from other social sciences (Düppe and Weintraub, 2014). The joint of this development was the application of the axiomatic approach in mathematics to general equilibrium theory. The early contributions to this development were mathematical existence proofs written by John von Neumann, John Nash, Kenneth Arrow, Gérard Debreu, and Lionel McKenzie (using various versions of Brouwer's fixed-point theorem, see Weintraub, 1983; Debreu, 1987). This launched the period of several decades of advancing mathematical tools in order to determine axioms that are necessary to prove, next to existence, uniqueness, stability, and the optimality of an equilibrium (Ingrao and Israel, 1990). By the 1970s, definitions of equilibrium conditions (the axioms) became a necessary requirement for all economic theory.

The axiomatization of equilibrium theory was, similar to mathematics at the same time, coined by an 'image conflict' (Dalmedico, 2001). In the spirit of John von Neumann, several mathematical economists understood the axiomatic approach as a clarification of the behavioral and institutional elements of equilibrium theory: producers and technologies, consumers and commodities. Axioms are seen as basic ontological properties that must be true for an equilibrium in a competitive economy to possibly exist, to be empirically determined (uniqueness), to be stable, and to have desirable welfare properties (optimality). The early existence proofs were

considered a preliminary exercise that would generate new solutions to traditional questions (Arrow, 1968). The success of the axiomatic method would depend heavily on the plausibility of its axioms as being descriptive of economic reality. Specifically the rationality of optimizing agents emerged as the pivotal condition of equilibrium.

According to another image of the axiomatization of equilibrium theory, however, the mathematical structure of the theory is only loosely related to its possible interpretations. Innovations of new mathematical tools can then enlarge, limit, or create new forms of explanations on the level of economic theory. Several mathematical economists, many of which were associated with Gérard Debreu, focused on the development of new mathematical tools such as measure theory and nonstandard analysis, among others. The guiding epistemic virtue was mathematical generality (which does not necessarily correlate with greater economic applicability): topology being more general than, for example, differential equations. As questions of stability, among others, required tools that are lower in this hierarchy than those necessary for existence proofs, the latter played a greater role than the former. The pivotal axioms that emerged from this axiomatic approach were properties such as convexity, monotonicity, differentiability, continuity rather than the behavioral notion of rationality. Moreover, equilibrium analysis was not related to competitive institutions, a concept that does, for example, not appear in Debreu's *Theory of Value* (1959). The axiomatic method results in the separation of mathematical and economic reasoning that has indefinite and uncontrolled effects on the latter.

This image conflict was hardly ever confronted such that there was never a consensus among practitioners in economic theory what the exact status of axioms is: hypothesis, basic ontological property, or auxiliary construct for creating a plurality of contextual theories (Düppe, 2012). Accordingly, the concept of equilibrium, until today, plays a double role in economic theory: it refers to the analytical solvability of a model, and at the same time to the solution concept of actual economic problems by modeling the consequences for an entire system. After the diffusion of general equilibrium models in the entire discipline during the 1970s, the concept drove a wedge between the analysis of theoretical structures and the elaboration of economic interpretations.

Within the inner circles of mathematical economists, however, the research program of axiomatic general equilibrium theory showed rather negative results: stability could not be specified, uniqueness of an equilibrium required ad-hoc assumptions that were considered rather strong, and at the top of it, in 1974, Hugo Sonnenschein, Rolf Mantel, and Debreu showed that excess demand functions lack structure even if one assumes well-behaved, i.e., rational individual preferences. The theory imposes little structure on empirical data. Even simple questions of comparative statics (such as the effects of tax cut on demand and supply) that were already by the 1960s and still are standard in economic education could no longer be considered rigorous. One has to impose additional structure in order to generate empirically definite results (such as constant elasticity of utility functions, a specific income distribution, and the like).

By the mid-1970s, the hopes of early post-World War II years for the future of general equilibrium theory were largely disappointed. Mathematical economists such as Frank Hahn, however, considered these negative results most valuable insofar as they allow for a falsification of the beliefs that were traditionally linked with the notion of equilibrium, above all its normative aspects (Hahn, 1973). In terms of the present article, axiomatic analysis of equilibrium theory helped correcting the beliefs that the analogical concept of equilibrium has established.

Game Theoretical Concepts of Equilibrium

After John von Neumann's and Oskar Morgenstern's seminal book, *The Theory of Games and Economic Behavior* (1944), also game theory, with a certain delay, transformed the concept of equilibrium. One research question that has been pursuit during the 1960s was specifically formative, that of 'core convergence.' The core is an equilibrium concept going back to Edgeworth's theory of exchange: it includes all allocations, for which no subset of individuals would be better off, if they separated from the other individuals (in the case of two individuals, the core excludes those allocations, which leaves individuals worse than alone). The question of core convergence was whether or not, once the amount of individuals increase, the set of core allocations shrinks toward the competitive price solution. Core convergence thus opened a path to integrate game theory in the tradition of economic theory enlarging the scope of equilibrium theory from competition to strategic behavior. In fact, competitive behavior appeared to be a special case of noncooperative games – 'oceanic games,' as Milnor and Shapley called them (1961). Core convergence helped in "rescuing" the standards of mathematical modeling that were established in general equilibrium theory where they led into the rather negative results mentioned above (Rizvi, 1994).

Historically speaking, this revival of game theory in the 1960s bore aspects of irony. The 'core' referred back to another, slightly more general concept in cooperative game theory, the 'stable set.' Cooperative game theory allows for some coalitions to be binding even if some individuals would be better off without partaking in this coalition. This was the central equilibrium concept in von Neumann's and Morgenstern's book (1944). Mostly because of the interpretations of the Austrian trained economist Morgenstern, game theory was initially presented in contrast to competitive equilibrium as the latter excluded the exertion of strategy and power. This opposition was forgotten once competition was considered to be analytically reducible to game theory.

The most dominant equilibrium concept in game theory, however, is the noncooperative solution concept named after John Nash: no player can gain by changing behavior unilaterally taking into account the behavior of other players. The existence proof of such equilibrium was an inspiration also for Arrow and Debreu to proof existence in general equilibrium theory (Düppe, 2012). Further refinements of the Nash equilibrium became central to all game theory, causing an entire industry of research elaborating information constraints imposed on all or a subset of players: different kind of games (asymmetric games, sequential games, mixed strategies, evolutionary games where players act according to (genetic) traits), different market forms (for

example, Cournot equilibrium in a duopolistic market, or Lindahl equilibrium as a solution to public good problems), but also different types of auctions. Game theory, much in contrast to general equilibrium theory, is thus considered descriptive of behavioral content and institutional contexts. None of its institutional applications, however, replace the concept of Nash equilibrium.

Game theory also proved to be crucial for the import of new empirical methods into economics, such as cognitive theories and experimental methods. The results, however, concern the behavioral assumptions, but not the concept of equilibrium itself. It is still difficult to imagine a theory identifiable as economic theory without reference to the concept of equilibrium.

Equilibrium Analysis in Today's Macroeconomics

Despite the fact that competitive general equilibrium analysis, as shown above, has turned out to imply little for empirical research, it continues to be the sheer exclusive reference point, in combination with econometric methods, for all macroeconomics theories. General equilibrium theory has been omnipresent ever since the work of Robert Lucas, Thomas J. Sargent, Edward C. Prescott, and among others (Snowdon and Vane, 2005). It is used as the analytical solution to so-called dynamic stochastic general equilibrium models. These models use the general equilibrium framework subject to stochastic shocks in order to explain historical time series data given calibrated exogenous variables. The analytical problems stated in axiomatic equilibrium analysis are bypassed by imposing structure on economic agents (usually Cobb–Douglas functions, which brings back the representative agent of Marshall's partial equilibrium analysis).

After the 2008 financial crisis, dynamic stochastic general equilibrium (DSGE) models and with it the imperative of equilibrium analysis was put under heavy attack (Colander, 2010). Even though in newly emerging fields such as in econophysics the concept of equilibrium appears to be expendable, since agent-based simulation techniques bypass analytical solvability of mathematical modeling, the great mass of macroeconomic theory is far from incorporating these tools and moving away from equilibrium analysis.

Equity and Education

Abstract

Equity and education are long-standing goals of many societies and there are diverse perspectives on ways to provide equal opportunities and resources for all. The literature reviewed reveals wide differences in educational outcomes both within and between countries and suggests that education policy and institutions on their own cannot solve structured inequalities. It is also argued that in a time of economic liberalization equity in education in many countries is more difficult to attain and that inequalities can be deepened. Research indicates that social mobility is more difficult to achieve for students from lower income households who continue to receive poor quality education and therefore social hierarchies and opportunity structures remain intact. The literature suggests that public policy can make a difference and cites Korea, Malaysia, and China as examples of countries, which have performed strongly in international tests. Researchers argue that what is required is collaboration between all involved to fulfill the promises that education can empower all citizens to participate in a globalized world.

Introduction

Equity is usually defined as fairness, impartiality, and justice and is related to equal opportunity (Sen, 2009). The world's progress toward these goals is usually measured by comparisons across countries and involves many disciplines. A review of the literature suggests that in many contexts equity inspired goals are not always realized and where they have been attained political and economic changes can reverse equity gains. The key reasons cited for not achieving equity are that not everyone has equal resources and structural poverty excludes those who are poor or cultural and religious practices are discriminatory against gender, age, diversity, or disability.

Education is seen as having positive effects on society by providing skills and promoting social stability, inclusion, and in creating modern democracies (Stromquist, 2005). It is also signaled as a major factor, which would make an impact on reaching equity goals and decreasing poverty.

Equity in education is usually linked to equal access to formal education opportunities and resources. The idea often assumes economic growth and social transformation. Equality of opportunity is generally considered to maximize the total social good, increases social gains, and can lead to diffusion of power to individuals. Education is seen as determining opportunity of outcomes, livelihood, and economic growth. The lack of education is often perceived as the most pervasive cause of inequality and underdevelopment. The immense technological changes that are synonymous with globalization have compressed time and space with the use of the Internet and electronic media. Alongside these are innovations in education technology which have given rise to new measures of equity and inequalities in education such as technological access and the digital divide. The new technologies have also renewed a focus on the significance of lifelong learning (LL) for adults.

Others argue that there are also prejudices against those who are not considered intelligent and this leads to variability so everyone does not receive the same education. In a similar vein, analysts and theoreticians conclude that the quality of education varies for different income levels with those at the lower end receiving an inferior education and thereby the levels of inequality remain static or increase unevenly.

The Gini coefficient a common measurement of income inequality within countries captures the ratio between the most and least wealthy in a country with zero equating to zero inequality and one indicates complete inequity. This gap between rich and poor has increased in most countries in spite of more spending on education. A comparison of the Gini coefficient between countries show a wide range with one of the most equal countries such as Denmark scoring 0.248 and one of the most unequal South Africa scoring 0.65 http://data.worldbank.org/indicator/SLPOV.GINI. The implications for equity in education is that those with less income are less likely to receive a good quality education or be able to access tertiary education to enable them to find better employment opportunities.

Similarly, the human development index which measures longevity, health, and knowledge track a higher score for the North than the South. The human poverty index which measures life expectancy, adult literacy, water quality, and underweight children confirms the above data and indicates that Central Africa is the worst off region, while Japan has the best score www.wacra.org/world%20Poverty%20MAPPDF. This has led social theorists to conclude that education is but one force among many to distribute resources (Stromquist, 2005).

Education has evolved from the pursuit to attain knowledge for itself to include to lead, train, and nourish, as well as to see the improvement of societies and nation-states. On an individual level the outcomes are measured by the attainment of knowledge, skills, and an understanding of what is learned and an increase in cognition. The learner's identity and character may undergo change and the learner may become more socially responsive and also be desirable that the learner's ambitions are expanded and curiosity sparked and he or she aspires to seek and to create more knowledge, to be critical, for personal or economic advancement or pleasure, for social purposes, justice, and to excel in educational pursuits.

On a societal and country level the outcomes are measured by comparisons done by international agencies, such as the World Bank, The Organisation for Economic Cooperation and Development (OECD) by using the Programme for International Student Assessment (PISA) and the International Association for the Evaluation of Educational Achievement. Some of the measurements used to determine the quality, effectiveness, and impact of education are, the improvement in the quality of life and longevity, adult literacy, knowledge held in a society, returns on education, numbers, and progress of girls in education, how well students are prepared for life and the global economy, the income gap, as well as social and political stability http://www.OECD-ilibrary.org/education/education-indicators–in-focus_22267077.

Education in a formal sense means an institutionalized system wherein one enters a program of learning which is certified. It includes preprimary, primary, secondary, and tertiary pursuits which involved academic or vocational knowledge and skills and is strongly linked to employment opportunities, social mobility, and transformation.

The state is the main provider of education at a primary and secondary school levels and in most countries subsidizes tertiary education. However, in a rapidly changing global context and with the financial instability since 2008, many governments have cut spending on higher education. In response, there has been a growth in distance education and privatized education provided by business and independent education institutions. Distance education provided by universities is a means to secure funds and to reach a global audience. These measures have meant that education for profit has gained in ascendancy in some countries and threaten to reinforce social hierarchies and opportunity structures.

Another economic factor, which has impacted on equity and education in the early twenty-first century is a downturn in the global economy. This has led to high rates of youth unemployment which subsequently impacts on access and success in education with implications for economic growth and social and political stability (Scarpetta et al., 2010). Researchers point to other challenges in achieving equity in education linked to technology and new forms of social media which have resulted in changes in the global culture especially among youth. These new methods of communication bring to the fore the need for new and complex understandings in dealing with tensions between local and global cultures that defy attempts at homogenization within and across education systems.

There is a radical viewpoint (Morley, 2012; Thompson, 2000) which suggests that education does not necessarily increase social mobility but can reproduce inequalities by providing opportunities and resources for those already established in the society. Breault and Lack (2009) argue that factors such as the family capital (incomes and educational level of parents) represent an essential barrier of educational possibilities of graduates of public high schools and also that there is a considerable inequality even of educational intentions for lower income pupils as issues of equity in these schools are steeped in deficit notions of fixing the problem. They further argue that children from families with higher social positions receive full secondary education and then go on to study in universities, while children from families with low family capital are limited by the general secondary education and then study in technical colleges. These views are supported by empirical research conducted by UNESCO and the OCED (2010) PISA study done in 2009 shows that many 15-year-olds who performed poorly in PISA tests are from socioeconomically disadvantaged backgrounds and that poor home backgrounds reinforce low-quality performances.

Nonformal and informal education or learning usually means noncredit learning, which takes place outside of formal institutions and can occur in the everyday. This kind of education is usually led by nongovernmental or civil society organizations, trade unions or occurs in social movement activities. Internships, apprenticeships, or on-the-job training are other forms of nonformal learning and can play a role toward accreditation. In many parts of the world like in India, or in some parts of Africa many people learn in the informal system as they do not have the resources or cultural practices forbid girls to attend school (Rogers, 1992, 2005).

Nonformal programs offering literacy programs have experienced uneven successes. The successes in Cuba and in the previously socialist and communist countries have not been replicated in most of the developing countries (OECD – World Inequality Database on Education). Women and youth in rural areas in developing countries still constitute the bulk of the target group for nonformal education (Rogers, 1992, 2005).

The impact of nonformal education is not easily measured and learning in social movements is usually measured by social change, how power is redistributed, and the growth of democracy (Rogers, 2005). These are significant measures of equality in new democracies such as in South Africa which gained a new democratic government in 1994 and in Tunisia and Egypt where, in 2012, social movements unseated the ruling powers. This phenomenon is now widely known as the Arab Spring. Govender and Chinna Rao (2012) point out that the victories in these countries over the past few years may not necessarily have replaced unequal relations or changed societies fundamentally.

Interventions to Achieve Equity in Education

The most significant intervention to achieve equity through education on a global scale has been to provide free and compulsory primary and secondary schooling for children or what is often referred to as basic education. The provision of basic education on a mass scale is seen as a significant factor in increasing people's life chances. A quote from UNESCO's International Education statistics of the global population of primary school age states that at present 655 million children are in school and 61 million of children are out of school. UNESCO estimates that this number has declined but of this half is in Africa (www.unesco-MDG.org).

According to UNESCO progress to reach the Millennium Development Goals (MDG) and the goals set by the Education for All movement, one of which is to have universal education for all by 2015 is hampered by the continuing wars in Africa, ethnic prejudices, migration, HIV/AIDS, and tuberculosis, as well as malaria. Other factors that contribute to not reaching the MDGs are that in some communities in particular in rural areas girls are often excluded from formal secular schooling in

spite of great efforts being made by governments and women's movements to bring awareness of the importance of schooling and also to offer single sex schooling. The increase in the statistics for girls in schools in urban areas can be attributed to modernization which has meant an increase in urbanization and therefore the necessity to be independent and education is seen as one means to achieve self-sufficiency (www.World-Inequality-Database-on-Education). The increase of rural education is another feature of a country's path to development and in some countries, for example, in China it is hoped that improved rural education will slow down the rural population's movement to the city. In a study to measure the quality of rural schooling in Malaysia conducted by Othman and Muijis (2012) they found that generally teachers perceived no differences between urban and rural schools in educational quality.

There has also been an increase in religious schools attributed to religious fundamentalism and an increase in home schooling as parents become disaffected and prejudiced against multiculturalism, and the academic standards of public schooling.

Another feature of globalization has been the continuous migrations of populations all over the world, as well as an increase in the number of economic and political refugees. An OCED study of 2006 concludes that 175 million people live outside their home country and in OCED countries there has been an increase of 5% in the immigrant population between 2000 and 2009. New forms of discrimination against immigrant populations or economic or political refugees are on the increase as these populations are excluded from participating in everyday activities in the host country. In some countries, where there is high unemployment migrant populations often become targets of abuse. Governments, which abide by the United Nations Refugee policies, have allowed migrants and refugees access to education as it is acknowledged by them as a basic human right. This policy is also seen as contributing to political stability; it allows for the attainment of citizenship, for refugees to make a positive contribution to social cohesion, and contributes to human development. There is very little research to monitor progress in this area and no proven statistics to indicate that these attributes have been achieved. The 2009 PISA study indicated that immigrant populations are a significant community in schools who may not receive an equitable education. The PISA study showed that generally immigrant populations underperform in school. Some of the factors identified to explain underperformance are language barriers, poor learning opportunities, and public policies that do not take into account the diversity of immigrant populations (OECD, 2010–PISA study 2009).

Another significant intervention has been to provide access to excluded groups of people by participation to be inclusive of gender, religion, age, race, indigenous groups, or marginalized groups. Access into higher education of new constituencies is seen as a new form of democratization because it widens participation and is a form of social justice and contributes to economic development and social harmony (Thomas and Tight, 2011; Thompson, 2000).

Alternative admissions policies known as Recognition of Prior Learning (RPL) or Assessment of Prior Education and Learning (APEL) for mature adults were much publicized in the 1990s in higher education. These policies are associated with LL and redress and allow for alternative access for mature adults who do not have the required formal qualifications to use prior learning to gain access to an education program or to gain credit toward certification (Thomas and Tight, 2011; Thompson, 2000).

Widening access has not always meant that previously excluded groups have progressed seamlessly or have successfully completed their education, or excelled in their educational attainments. This has led to much research in the field of how to assist excluded groups from remaining in the education system and also to excel, as well as to allow them to become part of an academic community as staff and students (Thomas and Tight, 2011; Thompson, 2000).

A number of recommendations from the research have led to various reforms in education some of which are to create inclusive admissions policies and practices while making education provision available at convenient times and places for working adults. Opening up access to poor students has required financial assistance and scholarships, as well as measures to support academic development and in some cases the duration of the academic program has been extended. These reforms have to confront critiques of lowering academic standards in particular where admission requirements are lowered. The emphasis in most elite universities is on creating a meritocracy and maintaining an elite group (Featherman et al., 2010; Thomas and Tight, 2011).

In developing countries which have entered the global economy and have suffered racial oppression, colonialism, and imperialism like South Africa, India, and Brazil, and lag behind in professional skills there have been huge investments in education in particular in higher education. There have been concerted attempts to produce a skilled and professional work force. The interventions in these countries to end the inequalities have been to enhance schooling opportunities, which include more liberal admissions criteria, and a financial aid scheme financed by universities and the governments or a loan system to enter both public and private institutions (Akoojee and Nkomo, 2011; Featherman et al., 2010; Motala, 2001).

However, many students in higher education are academically underprepared because of an uneven schooling system therefore they are encouraged to attend extended degree programs. Because of the low numbers of skilled black people or professionals in South Africa in this population category there are various forms of affirmative action such as setting targets or quotas for certain programs such as medicine or careers such as engineering as these are disciplines and careers which were not offered to Black African students in apartheid South Africa (Featherman et al., 2010).

In Brazil, private higher education absorbs 70% because the public system is viewed as inefficient. This means that those who cannot afford the fees in private institution receive a low-quality education. In India, the impediments to access are poverty, the caste system, and gender discrimination impeded access to education. India has seen an increase in higher education and is now the second largest higher education sector in the world. The Indian state subsidizes higher education by almost 90% of costs and this has led to a huge expansion in higher education. However, state education is not always of same quality as in private institutions therefore there

has been a call for meaningful education for all (Akoojee and Nkomo, 2011).

Measures worldwide for schooling in certain countries have focused on improving equity by improving the quality of teaching which includes teacher training, encouraging progressive teaching methods rather than more didactic models that emphasize technical rationality. Other interventions for teachers have ranged from incentives in particular for rural teachers, apprenticeships, learnerships, workshops, in-house training, and professional courses. Alongside these innovations are calls for varied forms of assessment strategies such as including oral and written forms of assessments and to scaffold assessments, as well as to allow for cumulative and formative assessment models. Further measures to improve education performance and learning opportunities have ranged from increased physical resources, such as providing basic infrastructure for water and electricity, classroom facilities, improved instructional materials, calls for greater parent and community involvement, and incentives for teachers and principals (Othman and Muijs, 2012).

There is also a need for tutor assistance. In particular to adult students who often have to balance conflicting demands of work, family, and studies and may need more personal attention. Critical education theorists argue that a transformation in demography and different access routes such as RPL and APEL also require curriculum and pedagogy changes, as well as reforms in institutional structures and governance. They support the call for a critical pedagogy which supports social and institutional change as a means to improve equity (Thomson and Tight, 2011).

Widening access through use of technology commonly known as e-learning is also changing the way that teaching is practiced, how research is produced, and how knowledge is shared among teachers and learners and with the public. The uses of education technologies are changing pedagogic relationships and influence new theories of teaching and learning. Some argue that e-learning shifts more responsibility onto the learner however most are in favor and conclude that open access to resources via the Internet has empowered many people who otherwise would not be able to access knowledge. E-learning has increased social aspirations to an extent whereby societal expectations need to be taken into account in what is researched and how the knowledge is shared.

Other debates on this issue are that education should have a social justice approach and that such an approach should rely on dialectical, inquiry based, and interpretive strategies, which value critical reflection. Some social justice approaches argue that education should see the social engagement of universities and schools in community and social projects. Parents and communities should participate in governance, in curriculum, and pedagogy so that marginalized communities can be more empowered and express their own agency.

There are policy makers, educationist, and communities who wish to see changes in leadership and management and argue that democratic governance requires greater accountability and transparency from the leadership, as well as democratization of knowledge. There are also countercalls for education to be linked to social entrepreneurship in particular where there is a limited possibility of employment in the formal economy and more reliance on the informal economy (Breault and Lack, 2009).

However, research has shown that most of the interventions have limited impact and the success of these reforms is uneven. Even though education has progressed for many there are persistent exclusions based on a clear intersection of gender, class, race, and other forms of disadvantage. Therefore, theorists from multiple disciplines argue that education cannot overcome deep-rooted structural inequities and more serious attention needs to be paid to build a social movement that combine critical voices of the university, school leaders and staff, students, and the community to create a vision of the education that is a dynamic environment which includes love, energy, and determination to social justice and the attainment of equity (adapted from Breault and Lack, 2009: 165).

Measurements of Equity in Education

Education is viewed as a strong determinant of career, life chances, employment opportunities, life expectancy, and can contribute to social change and national development. However, employment opportunities are affected by labor market conditions and the dictates of demand and supply. Governments and industry are calling for a stronger link between education and the labor market and demands of the economy. But there is not sufficient evidence to prove that markets can determine education needs or the other way around.

OECD's equity indicators (i.e., schooling, earning, and employment) for the OECD countries measure how the global crisis has affected employment. These indicators illustrated that schooling and an upper secondary qualification is the norm in most societies for participation in the labor market and for entry and success at tertiary level, as well as integration into society and to participate in a globalized economy. OECD figures indicate that during the financial crisis people with a higher education qualification were more likely to be employed and have higher earnings compared to less educated people.

However, figures from 2004 to 2008 show some contradictions and indicate that during the economic crisis an upper secondary qualification among 20–24-year olds was no longer a guarantee to providing employment or decreasing poverty. In 2011, youth unemployment in the age range 15–24 years in the United Kingdom was at 21.9%. In OECD countries, youth unemployment was more than double the unemployment rate in the general population (17%) with an increase in Spain of 51%, Switzerland 7%, and in SA the figure was 52.5% http://www.oced-ilbrary.org/education.

Other forms of measurements dominated human capital theory or social efficiency are concerned with returns on investment. These approaches measure the relationship between inputs and outputs, the number of graduates in terms of the investment made, whether education achieves positive outcomes in the labor market, and a social efficiency perspective which argues that public expenditure on education must yield results anything less is wasteful expenditure. Educationists who favor an equity perspective oppose this view and argue that this discourse has led to tensions between equity and

efficiency with profound social consequences as poor performing schools face closure.

Stromquist (2005) and Othman and Muijs (2012) have argued for more qualitative studies which are attentive to history and culture to measure equity and efficiency with a concern for redistribution of educational opportunity and to improve the learning experiences of pupils. In their (Othman and Muijs, 2012) study in Malaysia to measure perceived differences in rural and urban schools they focused on processes rather than products and looked at the influence of education resources, school climate, parent involvement, and leadership (Othman and Muijs, 2012).

Equity Scorecards were used in a study in Ghana and Tanzania to measure responses to the MDG which is set to halve poverty by 2015 (Morley, 2012). The scorecards measured who was admitted, who gained access to which course of study, retention, completion, and levels of achievement. The data revealed that many poor students both men and women benefitted from widening participation policies but that academic choices are gendered and classed as both poorer and women students were underrepresented in Science and Technology programs and this suggests reproduction rather than transformation of social structures (Morley, 2012: 359). Similar results from Northern countries such as Australia where indigenous people have entered higher education from the 1970s also attributed low success rates to indigenous people having to fit into culture that is alien and one that does not empower marginalized cultures.

Further measures besides completion rates which ensure that there is accountability for public funds and investment in education is measured by the effectiveness of teaching and learning in education at a national level. Other measures are the number of students who successfully complete formal education and have the required graduate attributes which are often defined as changes in student lives and understanding of the world. Qualities which make them better and more responsible citizens, or better human beings, or social responsiveness and measures of redress are also measures of equity in education. Recently, the World Bank has also reported on the effects of corruption in government on achieving equity goals.

Some critical discourses argue that in a knowledge economy policy makers need to assert social values and work against pervasive politics of individualism and institutional competition in publication and research. They argue for more internal and international collaboration between researchers based on solidarities rather than contracts or rankings. They also favor publishing on the Internet in open access networks so as to make knowledge available to a wider audience and readership. In addition that publishing open source material should not be subject to copyright but publications be made available for public education and to encourage wider debate and discussion as this can stimulate common interests, solutions to issues and problems (Thompson, 2000: 182–183).

Conclusion

The notion of equity in education is important and has moved people in the past and will continue to move people in the future (Adaptation of Sen's use of social justice 2009: 402).

Education policies, interventions, and measurements point to a range of ideological positions which implies that the discussions are not neutral. However, there is substantial agreement among different positions that poverty structures access into education, success, and future mobility. Therefore, it is argued that what is required is the redistribution of resources as education on its own cannot deliver equality or erase all the inequities and cannot deal with all the social problems. The research indicates that the achievements are uneven and that social structures are reproduced, that the influences of global capitalism impacts on countries and people differently across the world and has sometimes deepened inequities.

The task to achieve equity through education is multilayered and will require the cooperation of governments, multinationals, social movements, academics, researchers, policy makers, and world institutions to seek innovative ways to achieve good quality education for all at the different levels of education so as to achieve the MDG for 2015. The alliances should also agree to shape a world responsive to social justice and solidarity (Stromquist, 2005; Govender and Chinna Rao, 2012).

Equity in Law

André-Jean Arnaud, Droit et Société, FMSH, Paris, France

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Equity is usually defined as fairness, impartiality, justness. Consequently, equity in law is said to exist when justice administered between parties appears as based upon natural reason or ethical judgment – whether or not it is in conformity with written (state) law. Indeed, equity can be considered either as a concept immanent to the law or as a set of principles outside the law, the function of which is to allow the judge to give soft interpretations in concrete cases in order to reach not too unmerciful solutions. Hence, equity is working at large in legal systems where the judge plays an important role, like common law or other systems where state law has a reduced role, while the official use of it is very insignificant in other legal systems, such as positivist continental laws. Equity in law can be examined under two main headings. Equity in law has always been considered (1) *ethically* as an opportunity to refer to equity against positive (state) law, and (2) *politically* as the way to open law to necessities borne from the economic developments.

Equity as a Common Expedient

In this sense, equity is positioned between law and ethics. In the Western legal tradition, equity was even culturally perceived as the only foundation of law. Equity and justice go hand in hand in Western legal philosophy. But the Roman root *aequus* was translated by two words that acquired two very distinct meanings through the ages: *equity*, on the one hand, and *equality*, on the other. The distinction led to opposing political theories on law and justice.

The Roman law defined legal work as skillfulness in settling what is good and fair : *Ars boni et aequi* (Celsius and Ulp, *Dig*., I, 1, 1, pr.). Among traditional legal principles, we find also the rule according to which equity must be expected in everything but above all in law (Paul, *Dig*., 50, 17, 90). As Pretorian law, a great part of everyday Roman legal regulation was progressively built upon equity in order to complete positive law. The Roman distinction between *ius honorarium* and *ius civile* has been seen by some authors as a forerunner of what would later exist in England as a distinction between common law and equity: a "body of rules existing alongside the original civil law, founded on distinct principles, and claiming incidentally to supersede civil law in virtue of a superior sanctity inherent in these principles" (Maine, 1861: p. 25).

Equity is used to replace legal rules drawn from statute or common law when these rules are considered too inadequate or unyielding for the expectation of justice in a specific case. Hence, equity was always considered as a common expedient against legal (state) justice where this latter appeared too distant from ethics, morals, or customs. This route to justice was historically employed to such a degree that the gambit was embodied in many legal traditions, re-emerging from time to time according to need.

In opposition to legal unfairness, equity is regarded as either a refuge (equity prompts legal rules to law givers) or a recourse (equity is the alternative source of a redress or remedy to those provided by established law).

From ancient times, equity was considered to be an efficient means to establish justice in law. Without equity, law would be unjust ('*Summum ius, summa injuria*'). Within legal anthropology, Henri Sumner Maine showed in his work *Ancient Law* that equity is considered an instrument to bring harmony to progressive societies. According to this author, equity is one of the three agencies by which primitive law has been adapted to the requirements of a developing society and an improving morality.

Equity was also considered in Western legal tradition as a complement or a corrective to positive law. There are a number of aphorisms on this topic, such as *Hæc æquitas suggerit, etsi deficiamur jure* or *Æquitas nihil aliud est quam jus quam lex scripto prætermisit*; that is, equity must be followed where there is no legal norm to reach a solution.

But, when the man in the street talks of 'equity,' he is thinking of ideal justice that may even be contrary to the law. Here lies that faith in the fairness of a claim to some natural law existing above positive laws or statutes. Equity focuses on the imperfections of law and can even be preferred to a legal norm where it provides a useful corrective to legal institutional justice by improving an equitable outcome: *Placuit in omnibus rebus præcipuam esse justitiæ æquitatisque quam stricti juris rationem*. Equity is better than a solution drawn from a strict interpretation of law. Such a theory, elaborated from Aristotle onward, runs through the Western legal tradition through Roman law, subsequent Canon Law (Grossi, 1998) and right through continental legal regimes before the French Revolution.

That law can be brought into harmony with society through equity is yet currently demonstrated by legal sociologists, whose research illustrates specific circumstances in which societies make appeals to alternative procedures where equity plays an important role. This is particularly clear when it is not ingrained within a culture to instinctively call on the law for help as the main way to resolve conflicts, such as in traditional Chinese or Japanese cultures. Moreover, equity is often grasped as an opportunity for a workable alternative to state law, where it is not envisaged by a written legal norm. In the last decades of the twentieth century, for instance, equity was cited in alternative movements by both Italian and Brazilian judges (*Alternative use of Law* and *Alternative Justice*, in Arnaud, 1993).

Equity as a Means of Adapting Legal Regulation to Political Prerequisite for the Development of an Economy

All through the building of the occidental legal tradition, while laws were considered as means to protect communities and ensure their reproduction following a specific pattern, equity also appeared as the way to open up law to necessities born from the development of trade. Here, equity appears (1) as an earlier technique to create a society for merchants, and (2) in the last decades of the twentieth century, as a means to implement a global legal order.

Equity as a Foundation of Trading Societies

At the end of the Middle Ages, the opposing pressures of the wish of kings to concentrate absolute powers in their hands, the opening up of everyday life to trade and merchants, as well as the emergence of a *bourgeoisie*, led the various national laws to adapt themselves to the development of landed and propertied interests. Western laws gradually expanded into opposing systems: the common law and equity tradition on the one hand and continental legal positivism on the other.

After centuries of legal rationalization, equity was definitively taken up from the discourse of ethics and located as one of the foundations of law, appealing to natural law and reason, even as against positive law and statutes (Hugo Grotius, Samuel Pufendorf, Christian Wolff, and their disciples in Northern Europe; Jean Domat in France).

As to the continental Romano-canonic tradition, equity was quickly made subservient to state law. Despite the influence of Domat's work on French jurisprudence, equity was forbidden in France by the *Ordonnance civile* of 1667. The French Revolution of 1789 was partially directed against the discretionary power of judges. A project to reintroduce equity as a tool in judicial interpretation in the French Civil Code was drastically cut down by Bonaparte. Finally, the judge was considered merely to be the mouthpiece of state law. It is true that we can find counterexamples in nineteenth-century France, such as judicial decisions by the *Bon Juge Magnaud* who used equity to avoid enforcing the law against the poor. But this use of equity was a rarity, and almost all such decisions were reversed by the court of appeal.

We can also identify some slight remains of equity in civil law, even in the French Civil Code (art. 565, 1135; 1854). The strongest examples are, however, drawn from the Swiss Civil Code, articles 1 and 4: "The law must be applied in all cases which come within the letter or the spirit of any of its provisions. Where no provision applies, the judge shall decide according to the existing customary law, and, failing which, according to the rules which he would lay down if he had himself to act as legislator. Herein he must be guided by approved legal doctrine and case-law – where the law expressly leaves a point to the discretion of the judge, or directs him to take circumstances into consideration, or to consider whether a ground alleged is material, he must base his decision on principles of justice and equity" (see Lloyd and Freeman, 1985: p. 1231).

At the same time, in the common law countries, legal developments went in the opposite direction. There, indeed, equity refers to that part of the law of England that is derived not from the custom of the realm nor the enactments of Parliament but from the decisions of the old Court of Chancery, consolidated in 1873, along with the other superior courts in the supreme court of judicature. Such equity pertains to a right recognized by a court of equity through a specific procedure. Here, we are faced with procedural equity and not 'natural justice.' Jurisdiction in equity is one of the three clearly marked divisions into which the jurisdiction of the court falls, together with a miscellaneous jurisdiction and a common law jurisdiction. The equitable jurisdiction of the court originated in the power that the chancellor assumed in the Middle Ages to modify a strict and formal legal system on moral grounds.

There are a number of principles used as guidelines when it is necessary to make appeal to this notion of equity: equity acts *in personam*; equity acts on the conscience; equity will not suffer a wrong to be without a remedy; equity follows the law; equity looks to the intent rather than the form; equity imputes an intent to fulfill an obligation; equitable remedies are discretionary; delay defeats equities; he who comes into equity, must come with clean hands; he who seeks equity must do equity; equity takes into account the balance of convenience; where there are equal equities, the law prevails and the first in time prevails; equity, like nature, does nothing in vain; equity never wants a trustee; equity aids the vigilant; equality is equity; equity will not assist a volunteer; equity will not permit a statute to be a cloak for fraud.

In England, because the remedies that the common law courts could give were early limited by the forms of writs available, men turned to the chancellor for equity. The two systems came to be administered by wholly independent tribunals whose decisions were frequently in conflict. The early jurisdiction of the Court of Chancery was in its nature extremely vague. From the beginning of the seventeenth century, it is possible to discern certain general principles in the exercise of the court's jurisdiction. The early seventeenth century was the principal turning point in the history of the court, for the common lawyers were seeking to prohibit the Chancery from interfering with common law rights. King James I resolved the conflict between the two jurisdictions in favor of the Chancery. From this time onward, although the conflict did not die down until the end of the century, the court gradually developed jurisdiction coordinate with that of the common law courts and on settled principles. In the eighteenth and nineteenth centuries, it came to follow precedent as strictly as they did.

The principal distinction between the two systems was that, whereas the rules of common law were supposed to have been established since time immemorial, those of equity could in almost every case be traced to the chancellor who invented them. In the nineteenth century the jurisdiction of Chancery, now clearly defined, was frequently classified according to its relationship to the common law as being exclusive, concurrent or auxiliary. By the middle of the twentieth century, the Chancery division consisted of the Lord Chancellor and judges divided into groups that were respectively assigned matters within the peculiar jurisdiction of the division.

In the United States, equity was developed with relative consistency during the nineteenth century. The expansion of the equity system was subject to statutory grants bestowed to

each state, which constitutes a specific feature of American legal history. During the Civil War, the equitable jurisdiction was generally attributed to courts of double jurisdiction. Since 1848, many states excluded the distinction between law and equity in favor of one 'civil action.' In the federal courts there was a complete fusion of law and equity by the adoption, in 1938, of the federal rules of civil procedure, promulgated by the US Supreme Court under authority of an act of Congress.

Equity as a Referent in the Framework of Contemporary Political Theory

Recently, the use of equity was proposed by neoliberal legal philosophers as a way to put into common practice some fundamental legal principles. Hence, equity has become a referent in the framework of globalization, re-emerging in many new areas for legal work, for example, private, regional, and international judicial assemblies, and directly in relation to global governance.

The importance of the recourse to equity in contemporary neoliberal legal and political philosophy is due to (1) the predominance of the Anglo-American legal tradition in international legal relations, (2) the special focus given to the above-mentioned principle according to which 'equality is equity,' and finally (3) the claim for a minimal state.

After much controversy surrounding the Aristotelian idea of 'corrective justice,' equity was reintroduced as the legal principle of equal treatment of people in the allocation of legal benefits and obligations. John Rawls designates as '*fair equality of opportunity*' the equity of opportunities that cannot be reduced to a merely hypothetical right (Rawls, 1971; para.14 and 46). Here arises a paradox: the more the state intervenes in establishing equality of opportunities, the more it stands apart from the ideal of contractualism that characterizes the minimal state. Consequently, there could be no coherent basis for imposing common global lawful and unique interpretations (for example, of human rights). This means that it would not be possible to universally expect the same behavior through all institutions, whether national, local, or international.

Popper's claim for the importance of tradition, a tradition that offers the moral structure of a society, is grounded in the idea that herein lies the social meaning of justice and equity. On the one hand, tradition reveals the degree of moral feeling that each society attains; on the other hand, should there be conflict between opposite interests, tradition is the moral framework that allows us to find fair or equitable compromises (Popper, 1963: Chap. 17, para. 3). Institutions alone give a society its legal structure appropriate to this moral background.

According to Friedrich Hayek, a free society – what he calls a 'great society,' similar to Popper's 'open society' – is a spontaneous order formed by individuals each pursuing their own interest. There is no common hierarchy of values; instead, a legal system that protects each individual's ability to pursue his/her own values provides the rules of behavior that discipline society and produce peace. Chief elements of such a legal system are the right to own property and the right to exchange one's entitlements on any mutually agreeable terms; the particular spontaneous order that arises when individuals exchange their entitlements is the 'market.' In Hayek's view, the market plays an invaluable role in harmonizing people's disparate plans: changes in the prices of goods give signals to entrepreneurs to produce more or less of different products, even though these entrepreneurs may be entirely ignorant of the causes of these price changes. Free, unplanned societies are thus characterized by greater order and less waste of resources than can ever exist in a planned society, which relies on a degree of explicit knowledge among the planners that can never be attained.

In the game of the market, each participant has equal formal rights. The results are unequal, but this is not unfair, Hayek explains; indeed, the possibility of such inequality (for example, between entrepreneurs who guess consumer demand correctly or incorrectly, or between risk takers whose risks do or do not materialize) is what allows the market to harmonize individuals' plans and to use resources rationally. Success or failure must depend only upon each person's action and cannot flow from the knowledge and power held by public authorities.

For Hayek, the 'great society' is not merely a national order; the benefits of the impersonal market order apply all the more as the great society is extended to the international level through globalization. Thus, inequality of results is also a characteristic of the global order, but equity is realized provided that everybody is treated equally according to these abstract rules of fair behavior.

States from time to time wish to introduce social justice through legal regulation. But equality cannot be implemented beyond equal treatment before the law. To the extent concepts of social justice seek to accomplish anything more, Hayek writes (Hayek, 1973), they require external planning, destroy the spontaneous feature of the market, prevent the great society from developing, and are thus incompatible with liberty. Moreover, redistribution between groups in the name of social justice produces conflict between groups. In other words, equality of result – even in the name of charity – or intervening to equalize opportunity, rather than equal treatment by law, leads to arbitrary outcomes. Concrete human circumstances may evoke compassion and lead to requests to modify the abstract rules. But, Hayek argues, humankind requires an impersonal global order to thrive, and meddling with the order to produce what he calls 'the mirage of social justice' reveals a lack of intellectual and moral maturity. Authoritarian intervention generates disorder and cannot be equitable. To speak of concrete common goals is specific to small closed societies in which people were protected by community at the price of their freedom. In contrast, a great society of free people can exist only if everybody submits to 'equal' abstract rules.

In this context, it is easy to understand that the state must play a minimal role. The 'entitlement theory' (Nozick, 1974) based upon a discussion of Hart's 'principle of fairness' (Hart, 1961) challenges the claims for state action aimed at implementing equality among people.

Where the state is striking space, the judge becomes a masterpiece in the framework of the legal structure. The judge enjoys extended powers in such a society. He has to correct permanently the disturbances within an order that is spontaneous, not artificial, and that tells people what they have to do.

Such a judge must decide in equity in the sense that he has to decide if people's behavior is appropriate to what can normally be expected in comparison with the common conduct of the members of the same group.

The law of the judges is a translation of what people have learned from their actions. Judges' function is to maintain a permanent and efficient order in people's behavior. The judge contributes to improving a given order, an order that must not be upset by changes within relationships between citizens.

Such contemporary theoretical views on equity are particularly significant. Globalization is promoting neoliberal views on law, justice, and equity. Indeed, equity has already become a common referent for regional and international courts of justice. This leads in turn to many ambiguities, for instance in the implementation of the European Union's *Equal Treatment Directive* against sex discrimination. This last rule is based on a general feeling of equity but supposes some affirmative action through community (state) intervention (see the *European Law Journal*, 1998; Posner, 1993: pp. 404–405). The same ambiguity can be found in the report by the Commission on Global Governance entitled *Our Global Neighborhood* (Commission on Global Governance, 1995). In this report, written at the request of the United Nations, we read that "Justice and equity are essential human values. Respect for them is indispensable for peace and progress… Where large number of citizens are treated unfairly or denied their due… discontent is inevitable and conflict likely." However, 'a concern for equity is not tantamount to an insistence on equality.' Therefore, equity 'does call for deliberate efforts to reduce gross inequalities, to deal with factors that cause or perpetuate them, and to promote a fairer sharing of resources' (Commission on Global Governance, 1995: p. 51). This is good as political principle, but what practical legal rule can flow from such abstract, inconsistent, and equivocal discourse?

Nevertheless, and despite the lack of general agreement on its relationship with equality, equity appears as a newly contemporary and significant notion that promises great possibilities for redesigning law making, the administration of justice, and the process of judicial decision making.

Recent Uses of Equity: A Contrast between Legal Tools and Social Claims

When speaking of equity today, one of the main problems is the confrontation between theories, ideas, wishes, and utopia about what must be equity, on the one hand, and the reality of trade, economic, and financial aspirations, on the other hand. In other words, modern usage of this term includes a conception of fairness and equality of treatment for people in disparate circumstances. Toward that end, one can identify claims about *social equity* (that there should be fairness in the elaboration and implementation of public policy, as well as in the equitable distribution of public services), *gender equity* (that, regardless of gender, people should be treated equally as human beings or as rights-bearing citizens), *race equity* (that, regardless of race, people should be treated equally as human beings or as rights-bearing citizens), and *pay equity* (that employees should receive comparably equal pay for comparably equal work).

The problems tied to gender, race, and cultures pertain to social equity, but more especially to *cultural equity*. This expression encompasses family background, child welfare, education, role models and mentors, experiences of gender and race-related issues, choice of field and career, professional and personal life goals. Teaching diversity and educating citizens in a multicultural society is becoming a global obsession, concretized down through the implementation of more and more national legal norms of affirmative action. Many colleges and universities consider the term *social equity* as synonymous with *social equality*. However, some argue that this is mere pretention to equality, and that it necessarily creates other forms of inequality (Messerli, 2012).

The recent uses of equity have complicated the meaning of this term in the legal and social universe. While some uses may appear to have appropriated the term, the notion of equity, through the development of claims to social equity, seems to be increasingly implicated both in social claims and in calls to redesign public policies and law making.

Equivalence and Transfer Problems in Cross-Cultural Research

Amina Abubakar, Tilburg University, Tilburg, The Netherlands; and Utrecht University, Utrecht, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Problems in transferring tests from one context to another arise from construct-, method-, or item- level bias. Using examples from research in different parts of the world, the author highlights and discusses specific problems in transferring tests across cultures. A systematic approach to making adaptations to tests and procedures to ensure their suitability in a new cultural context is presented. The approach has a strong focus on community involvement and the use of mixed method approaches during the test adaptation process.

Introduction

There are a large number of psychological tests and scales that are adequately standardized and normed for use by developmental psychologists; most of these are commercially available and widely distributed. However, a significant number of these tests have been developed and standardized for use in a very limited demographic and geographical setting i.e., largely developed and standardized among white middle class North American and European children and families. Consequently, most of these tests may not be culturally appropriate for use by other groups that were not included in the development and standardization procedures, unless their appropriateness has been shown. When developing a test, most test developers will, in their choices of items, tasks, stimuli, and administration procedures, be informed by what is happening in their immediate social, economic, and cultural contexts (Gopaul-McNicol and Armour-Thomas, 2002). Taking this scenario into consideration, the implication is that the cultural context of a significant proportion of the world's population did not contribute to the conceptualization of both the test contents and the administration procedures. Most researchers and clinicians in emerging and developing parts of the world find themselves lacking the necessary tools and measures to assess child development and outcomes.

Cultural influences may lead to several forms of bias in cross-cultural assessments that do not carefully consider the impact of test transference into a new culture (Van de Vijver and Tanzer, 2004). Three forms of bias can be distinguished: construct, method, and item bias (Van de Vijver and Tanzer, 2004). The first one is *construct bias*, which occurs when an instrument only partially samples the domains that define a construct (Van de Vijver and Hambleton, 1996; Van de Vijver and Tanzer, 2004). For instance, as the development of the modern intelligence test was based purely on Western definitions of scholastic achievements, it has a strong emphasis on aspects such as reasoning, memory, and acquired knowledge. However, in non-Western countries such as those in Africa, there is evidence that the conceptualization of intelligence has a very strong social aspect (Mpofu, 2001; Grigorenko et al., 2001). Consequently, the use of non-Western measures may not adequately measure intelligence in African contexts.

The second bias consists of *method bias*, which refers to problems that arise due to administration procedures, instrument and sample characteristics. Most assessment measures have laid down procedures and conditions for administration. It is usually assumed that all children understand the norms within the assessment context and would respond accordingly (Gopaul-McNicol and Armour-Thomas, 2002). However, it has been observed that in several instances, the test administration procedures may be culturally inappropriate (Foxcroft, 2002). Included in this are the examples of unfamiliarity with involving themselves in a one-to-one dyadic interaction with adults, unfamiliarity with directly responding to questions asked by an adult, and/or balancing between speed and accuracy. For example, in rural Kenya, children spend a significant amount of time with siblings; requesting such children to fully engage in a developmental assessment task in a one-to-one assessment with an unfamiliar adult led to significant problems in task engagement (Abubakar et al., 2007). However, introducing the test in the presence of a sibling and allowing the children to settle in gradually, enhanced their test engagement. Similarly, in a Singaporean study, it was noted that most children were too shy to express themselves in the presence of an adult; consequently, it was difficult to evaluate their expressive language.

Instrument characteristics such as stimulus and task familiarity have been observed to influence test-taking behavior and performance across different cultural contexts. Malda et al. (2010b), in a study in South Africa comparing children of Setswana and Afrikaans origin, observed that children from both cultural groups performed significantly better in tasks that involved items, vocabulary, and experiences drawn directly from their cultural settings. In an assessment of children from different cultural groups in South East Asia (Hmong, Laotians, Vietnamese, and Cambodians), several aspects of the Denver Developmental Test had to be modified due to their unfamiliarity with the test takers (Miller et al., 1984). For instance, language items that had plurals had to be excluded because none of the languages used by the children taking part in the study used plural forms. Additionally, they observed that while children of Cambodian origin could easily engage in 'pat-a-cake' play as part of the assessment, the children from the other cultural groups were unfamiliar with this game, hence could not participate in it.

The last form of bias is *item bias*. This may arise due to differential functioning of items in different contexts (Van de Vijver and Tanzer, 2004). For example, in a study in West

Africa, digit span was found to have significant bias against the Wolof-speaking children, because among the Wolof people, digits are counted to the base of five, while among the Mandika people, digits are counted to the base of 10. In this case, the Wolof-speaking children were disadvantaged because they had to remember much longer digits after the initial five digits (Jukes and Grigorenko, 2010). Moreover, in developmental psychology, item bias may arise due to differences in both speed and patterns of acquisition of developmental milestones. For instance, Vierhaus et al. (2011) observed that in the assessment of developmental outcomes among Cameroonian children using the Bayley Scales of Infant Development (BSID) scores, the performance of the Cameroonian children diverted from the expected patterns. While unable to perform some of the 'simple' motor tasks, they were nevertheless able to perform 'more advanced' tasks. Consequently, strictly following the discontinuation rule of the BSID may potentially underestimate the performance levels of Cameroonian children.

Dealing with Problems of Transference: Adaptation and Assembly

There are two options for dealing with problems of transference across cultural contexts: *adaptation* or *assembly* (Malda and Van de Vijver, 2005). Adaptation involves a systematic evaluation of all aspects of a measurement instrument, and modifying it where needed in order to make it more suitable to the context. Assembly involves the development of a new measurement instrument. These approaches are expensive and time-consuming. However, the availability of an instrument that has been developed and rigorously evaluated on-site significantly enhances the validity of the data collected (Van de Vijver, 2002). Whether one adapts or assembles a new tool will largely be informed by salient aspects of the study design. For instance:

1. Target sample: As previously discussed, sample characteristics largely influence test-taking. For instance, working in a context where there are no standardized tests, the needs of the rural and urban populations may vary. With globalization and exposure to westernized education, urban children may be more able to cope with tests from other contexts. However, this cannot be assumed; formal evaluations of the suitability of the measures need to be carried out before being used.
2. Target construct: Some constructs have been observed to have much easier transferability between contexts as compared with others. In our work in rural Kenya, we have observed that measures of motor development are relatively easy to adapt to the rural African context. In adapting motor development measures, our main challenge was ensuring that test material and administration procedures were appropriate to this context (Abubakar, 2008). However, concepts such as parenting have been observed to be much more 'culturally influenced,' making it more difficult to come up with adequate procedures (Abubakar, 2008).

Test adaptations have to address all sources of bias previously discussed, to ensure that the adapted test is appropriate for the context. Malda et al. (2008) have proposed a framework of the types of adaptations that need to be carried out in order to be able to present the appropriate results. The slightly modified version of the framework on areas that need adaptation is presented in Table 1.

Moreover, whether one has decided to adapt or assemble the literature, cross-cultural psychology advocates the use of systematic approaches in carrying out this exercise. Various guidelines exist on how to carry out adaptations. In the next section, the author presents a four-step test adaptation approach that is based on field work done in rural Kenya, and cross-cultural work done elsewhere (Abubakar, 2008; Holding et al., 2008). This approach involves four phases, namely, construct definition, item development, scale development, and test evaluation. In the next section, each of these steps will be discussed.

Construct Clarification: A Mixed Method Procedure

In this first stage, the aim is to clearly define the construct to be measured, as well as to identify behavior indicators of the construct of interest. During this stage, one seeks to understand the full behavior repertoire that needs to be assessed, adequate approaches for assessing the behavior, and the best way to access this information. The use of a mixed method approach allows for the elicitation of both *etic* and *emic* aspects of the construct to be studied.

Etic aspects refer to aspects of the construct that can be accessed from a context of universalism, i.e., aspects of the content, items, stimulus, and administration procedures that do not require changes or modifications. To attend to the etic aspects of the study, one is required to carry out a systematic

Table 1 A summary of the types of adaptations that may need to be carried out

Type of adaptation	*Explanation of the adaptation*
Construct-driven	These are adaptations aimed at including items or modifying items to ensure that the construct of interest in the target population is fully captured.
Theory-driven	These are adaptations carried out to take into consideration the theoretical underpinning of the tests. For example, ensuring that all digits in the digit span test are adequate.
Linguistic-driven	In this category, adaptations are carried out to accommodate differences in the language structure of the original test.
Culture-driven	These adaptations are made to take into account the norms and standards that are culturally defined.
Sample-driven	These are adaptations made to ensure the tests are suitable for the sample being studied. Included here are modifications to administration procedures to cater for literary levels and modifications to the test materials, to ensure that the study sample is familiar with the stimulus being presented.

review of existing literature in order to provide a critical evaluation of existing measures of the construct of interest, and help identify a suitable instrument and items to be used. The review process could result in various kinds of choices for the test developer. First, one could identify a single instrument whose characteristics make it the best possible choice; this test would then be selected for adaptation. For instance, in looking for a measure of intelligence for use in India, Malda et al. (2010), used the Kaufman Assessment Battery for Children, version II, 2004 (KABC-II) as the basis for their work. They then set out to make adaptations to ensure that the content and the stimulus were appropriate for the context. A second scenario is that a variety of tests are used, and items are 'borrowed' from different scales to form the basis of the new scale. In this case, one assembles a new measure based on existing scales. A third scenario is where one reviews the literature, does not use any existing items, but uses the existing theoretical information to design a tool.

Emic aspects refer to culture-specific aspects of the construct being studied, or culture-specific ways in which a construct understudy needs to be evaluated. The emic approach would involve quantitative data collection techniques such as focus group discussion, observation, interviews, and item rating with the members of local communities. In carrying out emic aspects of test development, two groups of the local community form an interesting target group. First, the local experts (by this the author means members of the community who are literate and possess expertise in the relevant areas): for instance, for a developmental psychology test development process, experts such as teachers, nurses, and local psychologists may be a valuable source of information. They provide the middle ground on information between what is in the literature and the community-level information. Second, the target community needs to be involved in this process; they provide the culture-specific aspects of the study. Moreover, by involving them, one is able to access information that tells them how best to access the data they need. Observing the natural setting in which people operate on a day-to-day basis allows for the formulation of the necessary procedures and skills. Methods for eliciting community understanding include Focus Group Discussions (FGDs), individual in-depth interviews, and direct observation. The role of the target community is diverse and may include definition of the construct in the local community, providing face validity of the item/tasks, and evaluating the cultural appropriateness of the items/tasks. For instance, in a study in Kilifi, consulting with the local population contributed to enhanced item wording of a translated version of the 10 Questions Questionnaire. In this study, though, they had used the forward- and back-translation approach for translating the measure; in the pilot stage, unacceptably high rates of 'impairments' in three specific areas were reported. In a series of focus group discussions with the mothers, it was indicated that the item wording in the local language had ambiguity. For example, the question on hearing impairments could mean the child either had a hearing problem or that the child is inattentive. In another example, use of local consultations has been dependent on access to local idioms and labels e.g., there is no Shona word for depression, but the term '*kufungisisa*' which means 'thinking too much' overlaps with depression (Patel et al., 1997).

Item Development: Translation and Formulation

The aim of this step is to prepare a list of potentially acceptable items, in clear and unambiguous language, through the integration of the information collected in Step 1. During this stage, items identified from the literature need to be translated adequately, while ideas identified from the community need to be adequately formulated into appropriate items so that they can be used in a scale. In the next stage, we look at issues related to translations and adaptations.

Item Translations

Various approaches to test translations have been proposed. One of the most popular approaches is the translation, back-translation approach. However, for several decades this approach has been criticized for being inadequate in providing an adequate translation of the original item. Brislin noted that the translation, back-translation approach has various problems. For example, the quality of the translation can be compromised when one has poor translators who stick to the grammar of the original language. This approach will make a back-translation easy; however, the scale will be inappropriate for the target. Furthermore, a back-translator may make sense of a poor translation and produce an adequate back-translation, thus covering up for the translation errors. We have previously used a process that combines the various translation processes to maximize the quality of the translated items. The steps in the evaluative process can be summarized as (1) Production of at least two forward-translations by two independent native speakers; the target of this stage is conceptual translations as opposed to literal translations. In ensuring a good translation, one has to select the most appropriate translators. Some of the important characteristics of good translators include being bilingual, being familiar in the cultural context, as well as being familiar with the construct one would like to assess. (2) Next, a back-translation of each of these translations is carried out. (3) A harmonization step, in which a panel of experts is formed to discuss and agree on the different versions. The panel of experts usually includes those involved in forward- and back-translations alongside the other experts; important here is the participation of a linguistic expert. During the harmonization process, the translations are examined in the light of the original text, and disagreements discussed until a consensus is reached. An adequate translation produces items that are conceptually equivalent, easy to read, natural sounding in the target language, and easily administered to the target population.

Formulation of the Appropriate Items

Item wording needs careful consideration. The simpler an item, the more likely it is to function well, especially within populations which have low literacy or who are unfamiliar with test-taking. Various studies in developmental and personality psychology indicate that items wording may impact on the validity and factorial structure of the measures. This may arise if the item is too complex (thus raising ambiguity), or if the items use negation (leading to careless scoring or results in response style in scoring e.g., extremity).

Scale Development: Refining the Scale through Pretesting and Piloting

At the scale development stage, activities include the full development of the scale, the development of scoring, and administration procedures. Training of those who will administer the tests ensures that the developed procedures are adequately implemented. Scale development involves a decision on how items are presented to the participants. This is done to take into consideration the characteristics of the sample and the local contexts. For instance, in the adaptation of measures of postpartum depression such as the Edinburgh Postnatal Depression Scale (Cox et al., 1987) for use in resource constrained settings, it was observed that mothers who were illiterate found it difficult to comprehend the measures presented in the four-statement formula. To deal with this problem, the statements were reformulated, and presented one after the other. The modification of the administration procedures led to enhanced comprehension, and validity of the adapted scale. Moreover, in developing scales one has to take into consideration the ability level of those who will administer the scales.

Prepilot and Cognitive Interviews

Having developed the scale, one has to evaluate test contents, administration, and scoring procedures in order to ensure their adequacy. At this point, test materials are modified as required. Various steps can be taken to ensure that the content is of good quality. One such step is cognitive interviews during the prepilot stage. These involve holding in-depth interviews with participants to elicit information related to how the participants understand the items, process the information, and respond to it. Some of the information one would attempt to obtain from this process is to what extent participants understand the questions in the way they were intended to be understood, and whether the items contain phrases or expressions which are either difficult, rarely used, or socially inappropriate. Cognitive interviews can be carried out either concurrently while the respondent goes through a questionnaire, or retrospectively as part of a debriefing discussion.

Test Evaluation: Psychometric and Nonpsychometric Approaches

In evaluating the quality of the adapted tests, there are standard psychometric and nonpsychometric approaches to be used.

Psychometric Evaluation

Following adaptation, an evaluation of the quality of the developed test is very important. The extant literature has sufficient guidelines on the psychometric approaches to be considered (Hambleton et al., 2005). The evaluation of validity and reliability of the tests is very important. Additionally, test norms for the newly developed or adapted tests need to be considered. If the scores of the developed tests are to be used for group comparisons, ensuring equivalence of the developed test scores is an important aspect of the developed procedures.

Nonpsychometric Approaches

Nonpsychometric information can be collected from participants, test administrators, or simply during the assessment session (Hambleton et al., 2005).

Observational Notes during the Tests

Data collected during the test session have the potential to provide significant information on the suitability of the adapted testing. Some of the relevant information here includes time taken to administer the test, and the reaction of the participants to test procedures, instructions and methods.

Feedback from the Test Administrators

Test administrators can provide valuable feedback on the quality of the adapted test based on the ease with which they were able to engage the participants, the ease with which they could administer the tasks, and the general quality of the interactions. If some tasks induced a negative reaction or uneasiness from either the test administrator or interviewer, a review of those tasks may be required to make them more acceptable.

Feedback from Participants

When working in communities where people are unfamiliar with the concept of psychological testing, it is helpful to get a participant to provide information on their experience in participating in psychological assessments. During such sessions, the participants can point out content, methods, and procedures they may have found difficult to fully engage in. This would provide the test developer with information on how to further improve the test, or alternatively information that can explain the patterns of results from the psychometric analysis.

Documentation

An important aspect of test development is to keep a good record of all test development and adaptations procedures alongside the psychometric properties of the newly developed test (Hambleton et al., 2005). The documentation of the adaptation process is important in providing evidence that the test content, procedures, and scoring are appropriate for all cultural groups, and that the context of the test is being applied. Documentation allows for interested parties to be able to trace the adaptations made. One needs to keep a record of different steps in the process, including the initial forward version, recommendations made by the panel of experts, the back-translation, problems faced during the pretest period, all modifications made, and the final version of the questionnaire used. It is also necessary to describe the samples used in this process (i.e., the composition of the expert panel and the pretest respondent samples). For the latter, the number of individuals as well as their basic characteristics should be described, as appropriate.

Conclusion

Transferring tests from one context to another presents significant problems that can threaten the validity of data. Systematic approaches to test development and adaptations

can contribute to the development of tests and procedures that are both culturally appropriate and psychometrically sound.

Erikson, Erik Homburger (1902–94)

James E Marcia, Simon Fraser University, Burnaby, BC, Canada

Abstract

Erik Erikson is an ego psychoanalytic theorist who developed a psychohistorical approach to human development and formulated an epigenetic sequence of ego developmental stages encompassing the human life span from infancy through old age. His theory provides a linkage between intrapersonal Freudian theory and social–contextual approaches to personality development. He emphasizes strengths accrued by the individual in the context of social institutions or rituals keyed to individual physiological development.

Erik Erikson (1902–94) emigrated from Germany to the United States in 1933. While working at institutions on both the east and west coasts of that country, he formulated his psychohistorical approach, which, in contrast to most other psychoanalytic schools, emphasizes the impact of social factors on personality development. Most importantly he provides a schedule for ego development extending from infancy through old age. His life span developmental schema consists of eight age-specific 'crises' in ego growth. Each of these has a somatic, social, and psychological component. The successful resolution of each crisis is important for optimal movement through the succeeding stages. The fifth psychosocial stage, late adolescence, is characterized by the crisis of 'ego identity vs identity confusion', the concept with which Erikson's name is most closely linked. Some of his best-known books are *Childhood and Society*, *Young Man Luther*, *Gandhi's Truth*, and *Identity: Youth and Crisis*. Although criticized by both 'left' and 'right' wing psychoanalytic thinkers and by some feminists, Erikson's theory remains one of the most influential, and researched, psychoanalytic theories of development. His work appears in almost all textbooks on human development as well as personality theory.

Erik Erikson was born on 21 June 1902 in Frankfurt, Germany, to a Danish Jewish mother, Karla Salomonsen. He was eventually given his stepfather's name (Homburger) and later christened himself, Erikson. He grew up in Germany, completed his gymnasium in Karlsruhe and in 1921 enrolled in art school. However, he soon left this and, after a *Wanderschaft* period, he secured his first professional position in the late 1920s as a teacher, together with Peter Blos, in Vienna's Heitzing School founded by Eva Rosenfeld, Dorothy Burlingham, and Anna Freud. The latter became Erikson's analyst and supervisor in play therapy with children. Erikson married a Canadian dancer, Joan Serson, in 1930. She was to become a significant influence upon, and contributor to, his life's work. In 1933, now the father of two sons, Kai and Jon, he left his incompleted studies at the University of Vienna, was voted a full member of the Vienna Psychoanalytic Society and emigrated to the United States with his young family. He established a private practice in Boston and was made a member of the Boston Psychoanalytic Society despite that body's parochial policy of limiting membership to physicians. During the next 5 years, Erikson worked at the Judge Baker Center in Boston, the Murray Clinic at Harvard, secured a position at Yale with the Gesell clinic and Institute of Human Relations, and began an important professional relationship with the anthropologist, Margaret Mead. In 1936 he became a father for the third time with the birth of his daughter, Sue. His fourth child, Neill, was born much later in 1944.

In 1938, Erikson, whose surname until this time had been his stepfather's (Homburger), changed his name to Erikson, became a US citizen and moved to California to take a position at Macfarlane's Institute of Child Welfare in Berkeley and established a substantial private practice in San Francisco in 1942–43. While working with returning veterans at the Mount Zion Rehabilitation clinic, he began a friendship with the Jungian analyst Joseph Wheelwright, who broadened Erikson's Freudian perspective. In 1949 he became a professor at Berkeley, in spite of lacking the usual academic credentials, but soon left after refusing to sign the McCarthy era loyalty oath – considered by some a 'Here I stand' gesture that may have prefigured his forthcoming book on Martin Luther.

In 1950 he presented his and Joan's outline of the human life cycle to a White House Conference on Children and Youth and saw his most influential book, *Childhood and Society*, published. He returned to the eastern US in 1951 to join the Austen Riggs Center in Stockbridge, Massachusetts, as clinician and author. There he established important professional and personal relationships with ego psychoanalysts Robert Knight and David Rapaport. At this time, he completed his second major book, *Young Man Luther* (1958). He published the monograph *Identity and the Life Cycle* in *Psychological Issues* (1959) expanding both on the life cycle outline and on ego identity, a concept, together with 'identity crisis' that was to become associated with his name in the mind of the public. The preface to this article by David Rapaport provides a valuable introduction to ego psychology in general and locates Erikson within that tradition.

With help from David Riesman and Robert White, Erikson moved from Stockbridge to Boston and Harvard in 1960 and became a professor, but outside of any particular academic department. In the midst of, and to some extent with reference to, the student unrest of the 1960s, Erikson began work on his second psychobiography, *Gandhi's Truth* (1969) for which he received both the Pulitzer Prize and the National Book Award. In addition, *Insight and Responsibility* (1964), *Identity: Youth and Crisis* (1968), and a revision of *Childhood and Society* (1963/1985) were also completed during this period. These books

reflected a growing shift in Erikson's thinking from the development of the individual, to the social context of individuals' development, to the moral and ethical implications of different forms of social organization for humankind. In this transition, the work of his friend, Paul Tillich, was influential. Clearly, Erikson had begun to move quite a distance from his orthodox psychoanalytic initiation by Anna Freud.

By the beginning of the 1970s, Erikson had become one of the most respected and honored thinkers within the psychoanalytic developmental area, described by one reviewer as 'the most influential of living psychoanalysts'. He delivered two sets of honorary lectures: the Godkin at the John F. Kennedy School for Government at Harvard in 1972, and the Jefferson for the National Endowment for the Humanities in Washington, DC, in 1973. These eventuated in two more books, *Toys and Reasons* (1977) and *Dimensions of a New Identity* (1974). Another book, *Life History and the Historical Moment* (1975), occasioned significant criticism from both feminists and New Left sources who found Erikson too politically and psychologically conservative.

Erikson's most important final writings were on the last life cycle stage of Integrity. These were *Reflections on Dr Borg's Life Cycle*, a commentary on Bergman's film, 'Wild Strawberries', *The Life Cycle Completed: A Review* (1982), and *Vital Involvement in Old Age* (1986) written with Joan Erikson and Helen Kivnick. A synthesis of Erikson's unpublished conference papers and manuscripts has been published by Hoare (2002). Erikson continued to do clinical work until 1990. He died on 12 May 1994, in Harwich, Massachusetts.

Erikson lived through the world-shaping events of the twentieth century: World War I, the Great Depression, World War II, and the United States' social–political Coming of Age in Vietnam. The national and ideological strands that the Erikson gathered up and wove into his psychosocial developmental theory were numerous: Danish, German, North American, Jewish, Protestant, classical psychoanalytic, ego psychoanalytic, existential, and even Jungian. His literary/theoretical excursions into a form of biography that he labeled 'psychohistory' further widened his intellectual scope to include Luther in Reformation Germany, Gandhi in preindependence India, Hitler in pre-World War II Germany, Gorky in Bolshevik Russia, and Jesus Christ in biblical Palestine. Although only one of a number of psychoanalytic thinkers who left Europe for America in the 1930s, only Erikson integrated and transformed these disruptive experiences into a clinically, theoretically, and empirically useful outline of the stages of normal human development. Two significant biographies on Erikson's life and work have been published: Coles (1970) and especially Friedman (1999).

In the beginning of his work, Erikson took a 'configurational' approach to children's play therapy, wherein he considered the spatial arrangement of items chosen by the child to be as important as the items themselves or the stories linking them. He carried this configurational approach over into his psychosocial developmental chart that portrays the human life cycle as consisting of eight central developmental crises, each having its more or less specific age-related time of ascendance. The first three stages: trust vs mistrust (infancy), autonomy vs shame, doubt (early childhood), and initiative vs guilt (play age) emerge from the Freudian psychosexual stages: oral, anal, and phallic. Erikson's stages of ego growth in childhood extend beyond their foundational Freudian erogenous body zones to include the development of associated modes of behavior (e.g., active and passive incorporation at infancy). A further extension of development from body zones and their behavioral modes is his description of specific stages of ego growth. These stages reflect the individual's senses of oneself and of the world and are shaped by the child-rearing practices of particular parents embedded within their particular culture.

The description of life cycle stages after childhood constitutes one of Erikson's unique contributions to psychoanalytic developmental theory. He continues his outline of a sequential ego development to extend beyond childhood through the adult years: Industry vs inferiority (school age), identity vs identity confusion (adolescence), intimacy vs isolation (young adulthood), generativity vs stagnation (middle adulthood), and integrity vs despair (old age). All of these ego developmental stages have their basis in physiological changes and all occur within the context of relevant social institutional 'rituals' (e.g., basic trust at infancy within 'motherhood'; industry at school age within 'schools' or other cultural child education practices, etc.). It is this grounding in bodily changes and their psychological significance for psychosocial growth that provides the basis for the theory's cross-cultural applicability. Finally, he also noted a schedule of associated 'virtues', which emerge from the resolution of each stage: basic trust > 'hope', autonomy > 'will', initiative > 'purpose', industry > 'competence', identity > 'fidelity', intimacy > 'fidelity', generativity > 'care', and integrity > 'wisdom' (**Figure 1**).

The emergence of each of the eight stages in this sequence is governed by an epigenetic principle comprising a built-in developmental progression of individual physical and psychological change occurring within a social context of age-related 'average expectable' demands and provisions. Because Erikson located personality development firmly within the social context, he is to be credited with initiating psychosocial developmental theory. Optimal development in childhood consists of a balance between the opposite poles described above, tilted in favor of the more positive alternative. Beginning in adolescence, resolution of a developmental crisis incorporates both poles into a synthesis. For example, identity development necessarily includes an element of diffusion or confusion; generativity formation incorporates some stagnation; and there is no integrity without some accompanying despair.

The primarily positive resolution of each stage is considered to be crucial for the resolution of the next stage. However, consistent with Erikson's configurational approach, there is an aspect to the design of his developmental chart that allows for remediation of inadequately resolved issues or precocious resolution of 'future' developmental issues. Each stage is assumed to arise during every chronological period, although the nature of that stage is shaped by the dominant issue of the period. For example, a basic trust vs mistrust crisis reoccurring at intimacy will take a form configured by the adult nature of relationships typical of early adulthood. Because they arise again at each succeeding chronological period, previously unresolved age-specific issues can be remediated through the provision of 'better-than-average expectable' conditions (e.g., counseling, psychotherapy, or enriched milieux). Similarly,

Figure 1 Psychosocial developmental diagram. Note that Erikson's original 'vs' has been replaced with 'and'. This reflects his thinking that stages are not a matter of 'either–or' resolution but involve a blend of the polar qualities, optimal development being a predominance of the positive pole. In addition, all squares in the chart are filled in to indicate that every stage occurs at every other stage.

because forerunners of succeeding stages are present at every stage, the theory suggests the possibility of precocious resolution of stages not yet encountered at the suggested chronological age.

In the broadest view, Erikson proposes that there are crucial periods ('crises') of development characterizing the human life cycle for which societies have developed institutions that, more or less successfully, furnish a matrix within which these developmental crises are resolved. Ideally, societal rewards and demands mesh with individual needs and abilities at each of these stages. Whereas Freud furnished a view of personality from the 'inside out', looking to the individual's unconscious in order to understand cultural products, Erikson, while accepting the essential Freudian dynamic principles, added a perspective from the 'outside in', beginning at the level of the whole individual and describing a particular culture's impact on human development. Also, in contrast to Freud, Erikson saw ego growth as continuous throughout the life cycle – from infancy through old age.

Erikson has been criticized from a number of quarters. Orthodox psychoanalytic theorists (e.g., Jones, Eissler) saw Erikson's emphasis on social factors and the ego in the development of personality as paying insufficient attention both to the causative role of early childhood experiences and to the primacy of unconscious factors in determining later adult personality. In short, they found him insufficiently 'Freudian'. Early feminist critics (e.g., Weisstein, Millett) took Erikson to task for his assumption of a unique developmental trajectory for women based upon their biological differences from men – in other words, too 'Freudian'. Later feminists (e.g., Gilligan) criticized him for paying insufficient attention to women's differences from men in terms of their capacities for care and relationship. Object relations theorists (e.g., Fairbairn, Winnicott) and self-theorists (Kohut) felt that Erikson was somewhat superficial in underemphasizing the importance of early mother–child interactions and overemphasizing the importance of social factors in personality development. By contrast, some historians and sociologists (e.g., Kushner, Weinstein, and Platt) have found Erikson's theory too little concerned with underlying causative social factors and questioned the universality of his eight-stage model. Social critics from the left (e.g., Fromm, Kovel) thought Erikson too conservative in his apparent acceptance of the social status quo. And, finally, social scientists (e.g., J. McV. Hunt) found Erikson's writing too imprecise to allow for empirical research. Erikson, himself, was critical of attempts to validate his theory with experimental methods, preferring more clinical and social approaches. The abundance of research that has emerged in the past 30 years largely vitiates the criticism of nontestability of the theory.

Erikson's primary contribution, emerging from the smoke of all the controversy noted above, has been a comprehensive overview of the human life cycle that incorporates somatic, psychological, and social elements. The influence of his psychosocial approach has been pervasive throughout ego psychoanalytic theory, developmental psychological research, and educational counseling, although there is no 'Eriksonian'

school of psychotherapy. Almost every psychology textbook on personality theory and developmental psychology of children, adolescents, and adults has a section devoted to Erikson. Although his descriptions of early developmental stages usually are covered, it is the identity issue at adolescence with which he is most closely associated, followed by his descriptions of adult life cycle stages. Even political theory, especially the 'politics of identity', has been influenced by his approach. Erikson has amended Freudian theory to make it more understandable, 'experience near', growth focused, researchable, and socially useful. Although criticized by classical Freudians, Erikson's extension of psychoanalytic theory into the realm of normal as well as optimal human development, may have saved that theory from its excessive interiority, pessimism, and obscurantism. In addition, because of its essentially interpersonal nature, Erikson's theory has provided a valuable link between drive-based classical and ego psychoanalytic theory and relationship-based object relations theory. From a social–political perspective, the psychosocial developmental outline proposed by Erikson is sufficiently clear and putatively universal that it can provide a guide for social programs that focus on establishing optimal conditions for human development across the life cycle.

To date, research has established validity for the last five Eriksonian stages: industry (Kowaz and Marcia, 1991); identity (Marcia, 1966; Marcia et al., 1993); intimacy (Orlofsky et al., 1973); generativity (Bradley and Marcia, 1998; McAdams and de St. Aubin, 1992); and integrity (Hearn et al., 2012; Walasky et al., 1983–1984). Kroger (2007) has authored a textbook on adult development. As well, two handbooks on identity theory and research have been published: (Marcia, et al., 1993) and (Schwartz, et al., 2012). Extension of Eriksonian theory into political psychology has been undertaken by Hoover (1997). A graduate school and treatment center based upon Erikson's theory, the Erikson Institute, has been established in Chicago. As well, an international society (Society for Research in Identity Development) and a related research journal (*Identity: An International Journal of Theory and Research*), both having their impetus in Erikson's work, have been in existence since 1998. Research on this theory continues into the present, much of it having to do with applications to child and adult development.

Abstract

This article demonstrates that contrary to some people's belief that Erikson is passé, Erikson is very much in fashion. It does so by providing an up-to-date, panoramic picture of the scholarship founded on Erik Erikson's theory of psychosocial development. It begins with a succinct introduction of the principal tenets of Erikson's theory and those of the most widely studied construct rooted in Erikson's theory – that of identity status proposed by James Marcia. Following this, are a critical analysis of the major critiques on Erikson's theory and a synthetic review of the chief efforts to improve the theory. The third part highlights empirical evidence supporting the validity of the Eriksonian stages and that of identity statuses. Finally, taking a firm stand on the recurrent, long-standing controversial issues over Erikson's theory, the article draws three conclusions – that Erikson's theory is highly relevant today and perhaps will be for a long time into the future; that it concerns both self and society; and that it applies to both genders. It is further contended that despite its limitations, the Eriksonian literature has practical implications for education and beyond.

Introduction

One of the major achievements in the history of psychology has been Erik Erikson's (1950, 1968) theory of psychosocial development. This article is divided into four parts. First, Erikson's theory and Marcia's (1966) concept of identity status are described. Second, principal critiques and the evolution of Erikson's theory are highlighted. Third, empirical findings rooted in the theory are reviewed. In the final part, some conclusions are drawn.

Theory of Psychosocial Development and Concept of Identity Status

Erikson first presented his theory of psychosocial development in his book, *Childhood and Society* (1950). Drawing heavily on the biological principle of epigenesis, Erikson articulated a sequence of stages during which ego development occurs, with each stage being related to all the others. Erikson's theory was profoundly influenced by Freud's (1894) psychoanalytic approach. However, as Hoare (2005) put it, as "the second stage psychoanalytic theorist" (p. 19), Erikson shifted Freudian thought "upward in consciousness, outward to the social world, and forward throughout the complete life span" (Hoare, 2005).

Central to Erikson's theory is the concept of identity. For Erikson, identity was multidimensional, to be viewed through a wide-angle lens. According to Erikson, an individual develops his or her identity through a sequence of eight stages that define the life cycle: (1) trust versus mistrust; (2) autonomy versus shame and doubt; (3) initiative versus guilt; (4) industry versus inferiority; (5) identity versus role confusion; (6) intimacy versus isolation; (7) generativity versus stagnation; and (8) ego integrity versus despair. Each stage is marked by a psychosocial crisis that is the product of the soma (body), the ego (psyche), and society. At each stage, the individual confronts new challenges and tries to overcome them, and each stage builds upon the successful completion of earlier stages. However, this does not mean that the pattern of individuals' psychosocial development is linear. Rather, it is cyclical in that the challenges of stages not successfully completed may be expected to reappear as problems at a later stage in life.

Over the years, Erikson's theory has engendered much theorization and empirical work, the most notable theorization being that of James Marcia (1966). Upon thoroughly examining the various common issues facing youths at the time, Marcia (1966) conceived the theoretical construct of 'identity status.' In particular, he elaborated Erikson's original adolescence stage of 'identity versus identity confusion.' According to Marcia, the criteria for attaining a mature identity are based on two essential variables: crisis/exploration and commitment. Crisis/exploration refers to the process during which adolescents actively examine developmental opportunities and identity issues, question goals and beliefs defined by their parents, and begin to search for personally appropriate alternatives in respect to occupation, goals, values, and beliefs. Commitment refers to the extent to which an individual is personally committed to self-selected aspirations, beliefs, goals, values, and an occupation. Based on the absence or the presence of crisis/exploration and commitment, Marcia characterized four identity statuses: identity achievement, moratorium, foreclosure, and diffusion (Marcia, 1966).

Major Critiques and Proposed Modifications

Like any other theory, Erikson's has had its share of criticism. This part first presents criticisms of Erikson's theory as a framework for understanding human development in the contemporary era. It then introduces major efforts to modify Erikson's original theory of psychosocial development.

Criticisms of Erikson's Theory of Psychosocial Development

Throughout the years, critiques of Erikson's theory have continued to appear from various perspectives, including those

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23200-5

of radical behaviorists, postmodernists, human developmentalists, and feminist writers. However, the criticisms seemed to be have been made in a piecemeal fashion, with a lack of dialogue among the critics. Largely due to this lack of communication, some scholars noted that there appears to be a growing consensus that Erikson is passé (Côté, 2002a). In response to the apparent loss of interest in Erikson's theory, Sorell and Montgomery (2001) posed what they saw as the three central questions concerning Erikson's theory. First, does the historical and sociocultural context in which Erikson's theory was constructed weaken its contemporary usefulness? Second, can a theory that ties individual development to a biological ground plan – hence placing strong emphasis on uniformity of experience – offer guidance for investigations into identity formed in the contemporary era, which is characterized by fast changing and multicultural contexts? Third, is the theory inherently androcentric and therefore unable to serve as a useful framework for understanding females', or even males', psychosocial development?

Concerning the first question, Sorell and Montgomery (2001) argued that Erikson's theory is a very useful guiding framework in contemporary settings, especially for identity research. The authors further contended that Erikson's theory distinguishes itself from all other developmental theories in that its construction was based upon a wide range of personal experiences and observations drawn from a variety of cultural contexts.

Regarding the theory's linking individual development to a biological ground plan, Sorell and Montgomery (2001) pointed out two problems. First, although Erikson extensively elaborated the link between biological maturation and psychosocial development from infancy through adolescence, he made no mention of the relationship between the two beyond adolescence. Second, Sorell and Montgomery (2001) noted that some had criticized Erikson for his 'anatomy is destiny' viewpoint concerning psychosocial development for males and females and the role that reproductive anatomy plays in Erikson's concept of self and identity. However, Sorell and Montgomery (2001) disputed this common criticism, stating that Erikson integrated the notion of biological ground plan into his theory of psychosocial development in a manner that is far more sophisticated than the 'anatomy is destiny' interpretation offered by earlier critiques.

As regards the third issue, Sorell and Montgomery (2001) believed that Erikson's theory is essentially androcentric because "it is organized by a definition of identity development as the construction of an individuated and separated self" (p. 113). They pointed out that only the first three Eriksonian stages have to do with caring relationships, thus supporting the viewpoint of earlier feminist writers (e.g., Archer, 1992; Gilligan, 1982) that Erikson's theory largely concerns males' identity development.

To stimulate scholarship on Erikson's theory, Côté (2002a) invited commentaries on Sorell and Montgomery's (2001) article. While they were either in agreement with or silent about the first two issues raised by Sorell and Montgomery (2001), the commentators largely diverged from Sorell and Montgomery on the third issue – the question of whether or not Erikson's theory is so androcentric that it is unable to describe females' psychosocial development. For example, Côté (2002b) convincingly argued that a balanced view of the selves can easily be seen in Erikson's notion of generativity, maintaining that Erikson had made it clear that the development of the stable sense of self is a logically necessary precursor to the establishment of stable relational bonds with others. Côté (2002b) further contended that Erikson's theory addresses the notion of care far beyond the first three stages. From an Eriksonian perspective, Côté concluded, the necessary condition for adulthood is a sense of active and caring responsibility for others, not only within one's own generation, but also for future generations.

Côté (2002b) was not alone in his view that Erikson did emphasize the relational self. Levine (2002) insisted that Erikson "always knew and, in fact, wrote about at great length" (p. 273) the dialectic of independence–interdependence. Kroger (2002) articulated her divergence from Sorell and Montgomery's (2001) view that Erikson's theory was androcentric at two levels. At a general level, quoting widely from Erikson's (1968) "*Identity, Youth and Crisis*," Kroger noted that Erikson's definitions of identity "continually emphasize the role of the individual and his or her interpersonal context as intricately intertwined in the development of ego identity" (p. 260). At a more specific level, focusing on Erikson's analysis of the notion of generativity, Kroger (2002) successfully made the case that generativity – the ability to care for one's offspring, one's work, one's community, and one's future generations – should be a task that is highly relevant for both genders.

Modifications to Erikson's Theory

Since the late 1980s, much effort has gone into modifying Erikson's theory of psychosocial development. One line of work has been the elaboration of Erikson's publications concerning adulthood. For example, based on Erikson's unpublished materials, Carol Hoare (2002) wrote a monograph, "*Erikson on development in adulthood: New insights from unpublished papers*," in which she provided an exhaustive account of Erikson's thoughts on what it means to be an adult. In particular, she lucidly interpreted Erikson's conceptions of such notions as insightful adult, wise adult, and mature adult. Further based on the published and unpublished writings of Erikson and on her interviews with Erikson's widow (Joan Erikson), Hoare (2009) wrote a paper in which she explored the meaning of spirituality in adult identity development, following the trajectory framed by Erikson – that of the progression from morality to ideology, to aesthetics, and finally to mature ethics.

While also focusing on an adult stage (generativity versus stagnation), Slater's (2003) work distinguished itself by adding new concepts to Erikson's (1968) epigenetic diagram, thus increasing the breadth of the central crisis of generativity versus stagnation. These new concepts of psychosocial conflicts include (1) inclusivity versus exclusivity, (2) pride versus embarrassment, (3) responsibility versus ambivalence, (4) career productivity versus inadequacy, (5) parenthood versus self-absorption, (6) being needed versus alienation, and (7) honesty versus denial.

Another major approach to modifying Erikson's work has centered on addressing the concern over the lack of association between biological change and psychosocial change beyond adolescence, and on proposing a ninth Eriksonian stage. In response to the criticism that Erikson's epigenetic theory did not describe the relationship between biological and psychosocial change beyond adolescence, Joan Erikson (Erikson and Erikson, 1997) expanded Erik Erikson's book published in 1982, elaborating at length both the biological changes and psychosocial changes concerning the 'integrity versus despair' stage and the implications of increased life expectancy in many contemporary societies. Furthermore, Joan Erikson added a ninth stage to Erikson's original scheme, focusing on the physical needs of the aging body and what they mean for integrity.

Joan Erikson's idea of proposing a ninth stage was reinforced by Forrest and Côté's (2002) discussion of what they called a subdivision of Erikson's eighth stage of life – "The mortal stage of late life." Forrest and Côté maintained that mortality presents "the optimal task of Realization (in many positive coping and existential senses) versus Denial (or other nonrecognition or emotional paralysis) or Fear (or apprehension or even terror)" (p. 329).

Finally, retaining the eight psychosocial crises in Erikson's (1959) model, Capps (2004) conceptualized each crisis and its resolution within the context of a decade. According to this reclassification, six of the eight stages occur in the adult years, thus reorienting the life cycle scheme more toward adulthood from early childhood. Moreover, Capps proposed a ninth and a tenth decade, with the ninth decade's central developmental issue being, again, 'basic trust versus basic mistrust,' and the tenth's repeating the life stage of 'autonomy versus shame and doubt.'

Empirical Evidence

Erikson's 1951 study heralded a line of research on the various Eriksonian developmental stages, while Marcia's (1966) empirical work marked the beginning of research on the notion of identity status (Eriksonian stage 5). Both lines of research have yielded findings that have not only lent strong support to Erikson's theory, but also helped to address some of the theoretical concerns previously discussed.

In this part, Erikson's theory of psychosocial development is examined in light of research evidence. It is divided into five sections. The first provides a brief survey of the research scope and methodology. The second reviews major work on testing the validity of the Eriksonian stages. The third highlights studies on gender-relevant concepts. The fourth introduces studies that examine the relationship between the Eriksonian stages and other variables. The final section underscores research on identity.

Scope and Methodology of Research

With the exception of some studies of young children (e.g., Archer, 1989a; Erikson, 1951; Wang and Viney, 1996), the majority of the studies have been conducted among college students and adults, with some specifically concerning the elderly population (e.g., Brown and Lowis, 2003; Hughes and Peake, 2002; Hannah et al., 1996; Zauszniewski and Martin, 1999). Furthermore, these studies have been undertaken in different parts of the world, with most of them having been conducted in North America.

Concerning research methodology, like many other areas in psychology, research on psychosocial development has been largely cross sectional. Moreover, studies investigating the Eriksonian stages have tended to employ self-report inventories that elicit responses to be scored on Likert scales, while those examining identity statuses have been much more likely to use such qualitative approaches as semistructured and autobiographical interviews, observations, and analyses of life history. Finally, between 1951, when Erikson conducted his first empirical study, and the first decade of the twenty-first century, when Luyckx and his colleagues (Luyckx et al., 2008) constructed the Dimensions of Identity Scale, more than two dozen inventories assessing the Eriksonian stages and the Marcian identity statuses were created (see the Appendix for a list of the major inventories identified in the literature).

Validating the Eriksonian Stages

Studies focusing on validating the Eriksonian stages fall roughly into six research themes. These include (1) validating the factor structures of inventories, (2) testing developmental differences based on age and attributes associated with adulthood, (3) investigating psychosocial development variations across times in different cohorts, (4) examining psychosocial differences in cross-cultural contexts, (5) studying the developmental trajectory for each of Erikson's eight original stages, and (6) validating the eighth and ninth stages.

Validating Inventories' Factor Structures

Over the years, factor analysis of Eriksonian-stage inventories has been carried out constantly. One such inventory is Constantinople's (1969) Inventory of Psychosocial Development (IPD) designed to assess the first six of Erikson's stages. For example, Varghese (1980) tested the IPD among 252 graduate students in the United States. Factor analysis of the scores from the 12 (six positive and six negative) Eriksonian subscales yielded two significant components. The first factor, named actualization, was composed of six variables that represented the positive aspects of personality: trust, autonomy, initiative, industry, identity, and intimacy. The second factor, termed retrogression, comprised six variables that symbolized the negative aspects of personality: mistrust, self-doubt, guilt, inferiority, diffusion, and isolation.

Another inventory is Rosenthal et al.'s (1981) Erikson Psychosocial Stage Inventory (EPSI). Factor analysis of the EPSI has also lent strong support to Erikson's theory. For example, Gray et al. (1986) tested the EPSI among 534 university freshmen and sophomores in the United States. Although the seven factors (e.g., initiative, industry, identity, friendship, dating, goal clarity, and self-confidence) obtained from the analysis did not precisely correspond to the relevant Eriksonian stages, each of the factors made substantive sense in supporting Erikson's observations on late adolescent development.

Several other popular inventories have also been submitted to factor analysis. These include, among others, the Ego Identity Scale (Rasmussen, 1964), the Ego Stage Development (Caillet, 1980), and the Inventory of Psychosocial Balance (Domino and Affonso, 1990). With very few exceptions (e.g., Caillet and Michael, 1983), studies examining the factor structures of the inventories suggest that the Eriksonian stages can be assessed by reliable and valid inventories.

Finally, it is worth mentioning that in terms of examining Erikson's construct of psychosocial development through factor analysis of particular instruments, some researchers have used multiple inventories, looking for a latent variable known as the general factor of psychosocial development (GFPD). For example, Dunkel et al. (2012) conducted a series of three studies among ethnically diverse university students in the United States. Results of correlational and confirmatory factor analyses in all three studies supported the hypothesized GFPD.

Age and Attributes Associated with Adulthood

One of the assumptions underlying Erikson's theory is that an individual's psychosocial development progresses with age. It is further assumed that people with higher levels of psychosocial development would display more attributes associated with adulthood. Such assumptions have been proved to be true by quite a few studies. For example, early in 1981, when Rosenthal et al. (1981) first constructed the EPSI, they tested their inventory among 622 adolescents (aged 9 and 11 years) from nine metropolitan high schools in Australia – after having pilot tested their inventory with 106 secondary school students (aged 9 and 10 years). The researchers concluded that, as expected, older students scored higher in the positive direction on each of the six scales assessed.

In developing their Modified Erikson Psychosocial Stage Inventory (MEPSI), based on that of Rosenthal et al. (1981), Darling-Fisher and Leidy (1988) found positive relationships of psychosocial development to age and attributes associated with adulthood. The researchers found that among 168 participants (aged between 19 and 86 years), age was positively related to generativity and ego integrity levels, and that those who reported exercising regularly scored significantly higher in the positive direction of the psychosocial attributes (also Brown and Lowis, 2003).

Psychosocial Development across Times

Support for Erikson's psychosocial development theory has also been demonstrated by the results from carefully designed cross-sectional studies. For example, Zuschlag and Whitbourne (1994) analyzed data from three generations of college students. Following up on Constantinople's (1969) classic study, the investigators administered Constantinople's (1969) IPD to two cohorts of students attending the same university in 1977 and 1988. The findings suggested that, for all three times of testing (i.e., 1969, 1977, and 1988) and for most of the Eriksonian stages, college seniors were more advanced in their psychosocial development than their younger counterparts.

Cross-Cultural Studies

Although very few studies have made direct comparisons between/among cultural groups, some scholars have pointed to a certain degree of universality concerning psychosocial development. For example, Wang and Viney (1996) compared the psychosocial development of school-aged Australian and Chinese students, using the Content Analysis Scales of Psychosocial Maturity (Viney and Tych, 1985). It was concluded that, although some differences in the individual scale scores were found between the two cultural groups, a general pattern of similarity was evident (also Zhang, 2010).

The Unique Developmental Trajectory of Each Eriksonian Stage

Two related basic tenets in Erikson's theory are (1) each stage normally reaches ascendancy at a particular time in the lifespan, and (2) despite each stage having an overall trajectory describing the average individual's progression through the stages, the interaction between individuals and environments could bring about individual differences in these developmental trajectories. These theoretical arguments have been supported by empirical evidence. For example, Sneed et al. (2006) conducted a 34-year longitudinal study with 175 adults in the United States, examining three of Constantinople's (1969) IPD scales: trust, identity, and ego integrity. As expected, each of the three stages showed a distinct developmental trajectory: the trust stage followed a positive linear trajectory; the identity stage followed a curvilinear trajectory that leveled off in middle adulthood; and the integrity stage followed a curvilinear trajectory with an increasing trend in middle adulthood.

Validating the Eighth and Ninth Stages

A number of studies have focused on the eighth and ninth stages – the extreme later life stages (e.g., Hannah et al., 1996; Hughes and Peake, 2002; Njus and Johnson, 2008). Although research on these extreme later life stages, especially research involving the ninth stage, is limited, the findings of this research support the validity of the ninth stage. For instance, Brown and Lowis (2003) examined the eighth and ninth stages among 32 women in their 80s and 90s and 32 women in their 60s in the United Kingdom. Results suggested a significant relationship of age to stage 9 but not to stage 8. Moreover, a statistically significant difference was found between mean scores of the two age groups for stage 9 but not for stage 8.

Gender-Relevant Differences in the Eriksonian Stages

Although one of the long-standing controversies over Erikson's theory concerns its usefulness in explaining females' psychosocial development, studies investigating this topic have largely reported gender differences as a by-product and of secondary importance. A number of such studies (e.g., Mellor, 1989; Zhang, 2013; Zuschlag and Whitbourne, 1994) found that women generally scored significantly higher on most of the Eriksonian stages, although the opposite finding has been reported occasionally (e.g., Rosenthal et al., 1981).

While studies focusing on gender-relevant differences are scarce, the findings of these studies are informative. For example, Mellor (1989) investigated the relationship between the first six Eriksonian stages and relational self-definitions

among 388 students in public schools in the United States. Results indicated that on three of the six stages (trust, initiative, and intimacy), males with separate self-definitions scored higher than did females with like self-definitions. Meanwhile, females with connected self-definitions scored significantly higher on the same three Eriksonian stages than did males with connected self-definitions. These findings, as noted by Mellor (1989), are in line with Gilligan's notion of gender-based self–other relationships.

Waterman and Whitbourne (1982) examined the relationship between sex-role orientation as measured by the Bem Sex Role Inventory (Bem, 1974) and psychosocial development as measured by Constantinople's (1969) IPD among university students and adults. It was concluded that the findings generally supported the view that the simultaneous endorsement of both masculine and feminine qualities was more conducive to adaptive capacity. The significance of this study lies in its telling finding that not only biological sex, but also sex-role orientation, matters in psychosocial development.

The Eriksonian Stages and Their Correlates

Since the late 1960s, the Eriksonian stages have been tested among different populations. Chief among these are senior adults and college students, particularly the latter.

Research on Senior Adults

Among senior adults, the Eriksonian stages have been examined against some positive attributes that are theoretically expected to be displayed by psychosocially well-adjusted senior adults and against a wide range of indicators of late-life maladjustment. Examples of these positive attributes include purpose in life, self esteem, and self-realization (e.g., Hannah et al., 1996); learned resourcefulness (Zauszniewski and Martin, 1999); and spiritual well-being (Hughes and Peake, 2002). Examples of maladjustment indicators are death anxiety (Fishman, 1992), depression (Hughes and Peake, 2002), and sleep disturbance (Wagner et al., 1983). As a whole, this literature provides strong support for the construct validity of the Eriksonian stages in that better psychosocial development is significantly associated with adaptive attributes, and lower levels of psychosocial development are significantly related to maladaptive attributes.

For example, Zauszniewski and Martin (1999) tested the relationship between the first eight Eriksonian stages as measured by the MEPSI (Darling-Fisher and Leidy, 1988) and learned resourcefulness as evaluated by the Self-Control Schedule (Rosenbaum, 1980). Research participants were 60 senior adults, aged between 65 and 90 years. Results showed that 37% of the variance in learned resourcefulness was accounted for by trust, autonomy, initiative, industry, and identity, whereas the contributions of intimacy, generativity, and integrity were not statistically significant. Such results led the researchers to conclude that the mastery of the developmental tasks through adolescence may play a critical role in determining how resourceful senior adults are in their daily activities. In another study, Hughes and Peake (2002) found support for their prediction that a better resolution of the conflicts in stages 8 and 9 would be related to a healthy sense of spiritual well-being.

A better resolution of the Eriksonian stages has also been proved to be significantly negatively associated with attributes indicative of maladjustment among senior adults. For instance, Wagner et al. (1983) examined the relationship of the level of resolution of the conflict between integrity and despair to sleep behaviors among 122 institutionalized and noninstitutionalized senior adults (aged between 60 and 89 years). They found that effective resolution of this conflict tended to reduce sleep disturbances. In another study, Fishman (1992) found that higher levels of ego integrity among 115 senior adults (aged between 65 and 93 years) were significantly correlated with lower levels of death anxiety.

Research on College Students

A broad spectrum of variables has been examined as the correlates of the Eriksonian stages among the college student population. These variables can be crudely classified into three types: cognition-oriented, affect-oriented, and behavior-oriented. A good number of studies have investigated the relationships between the Eriksonian stages and cognition-oriented variables. In the United States, for instance, Njus and Johnson (2008) tested their hypothesis that psychosocial development would be positively related to the need for cognition (NFC) – a social-cognitive individual-difference variable defined by Cacioppo et al. (1996) as the desire to engage in effortful thinking. The NFC scale and the subscale of Rosental et al.'s (1981) EPSI were administered to 200 incoming college students and to about half of those students again 15 months later. At both times, students who scored higher on the NFC scale also scored higher on the EPSI identity subscale. Among both Hong Kong and mainland Chinese university students, Zhang and her collaborator (Zhang, 2010; Zhang and He, 2011) found that creativity-generating and relationally oriented intellectual styles positively contributed to psychosocial development, whereas norm-favoring and self-oriented intellectual styles did so negatively. In Germany, Busch and Hofer (2012) found that high self-regulatory capacities benefited the development of intimacy among college students.

The Eriksonian stages have been tested against a range of affect-oriented variables, including academic motivation, self-esteem, purpose in life, internal locus of control, ego strength, anxiety, depression, and the Big Five personality traits. In Canada, Faye and Sharpe (2008) concluded that psychosocial development (as represented by identity and intimacy) played a critical role in facilitating academic motivation in college. Zhang (2013) concluded that among Chinese college students, the successful resolution of particular Eriksonian crises reversely predicted neuroticism, but positively predicted extraversion, openness, agreeableness, and conscientiousness.

Finally, the Eriksonian stages have also been investigated against behavior-oriented variables, including health behaviors (Schwartz et al., 2010; Wagner et al., 1983), career-decision behaviors (Cohen et al., 1995), and interpersonal behaviors (Ávila et al., 2012). For example, using multivariate Poisson regression analysis, Schwartz et al. (2010) found that higher scores on several measures of the Eriksonian stages were

negatively related to such health-risk behaviors as binge drinking, illicit drug use, sexual risk behaviors, and risky driving among college students. Among 423 college students, Cohen and his research associates (1995) found that higher degrees of successful identity resolution were related to higher levels of career decisiveness. Ávila concluded from two waves of data collection that identity development was predicted by romantic attachment, but not by parental attachment.

Research on Identity Statuses

Much more concerted effort has been devoted to studying identity statuses than to research on the Eriksonian stages. Since the mid-1960s, an extensive body of research validating the construct of identity statuses has emerged. To date, several insightful reviews of empirical work on identity statuses have been published. This literature indicates that results from the existing work can indeed offer answers to some of the major theoretical questions centered on the nature of the construct of psychosocial development in general and on the nature of the development of identity statuses in particular. Such issues concern the process, domain, timing, pattern/direction, and stability of identity development, as well as the identification of correlates of identity statuses. In all the studies concerning the aforementioned issues, gender differences in identity development remain predominant.

The process of identity development refers to the particular identity status typical of an individual's approach to arriving at one's self-definition. The key concern here is whether or not one is disposed toward exercising sophisticated decision making, as in the case of a moratorium identity status individual or an identity achiever. The domain of identity development refers to the particular content areas in which one's self-definition is formed, including family, ethnicity, ideology, sex-role orientation, religious beliefs, and vocation. The timing of identity development concerns the specific time in one's life when identity activities are taking place in different domains. The key question regarding timing is, do different domains become more salient for different genders as a function of different points within varying contexts? The pattern/direction of identity development concerns the trajectory of each of the four identity statuses. The basic developmental assumption is that all individuals go through identity diffusion, foreclosure, moratorium, and identity achievement – in that order. Finally, a related issue is the stability (or changeability) of identity statuses. The principal question here is, is it possible for individuals to regress from a more advanced identity status to an identity status that is indicative of lack of identity maturity?

Several independent reviews of the literature (e.g., Archer, 1989a; Cramer, 2000) have all concluded that adolescents and young adults generally demonstrate increasingly more sophisticated identity activities with increasing age. They have further concluded that research strongly supports Marcia's (1980) hypothesis that identity is mainly formed between the ages of 18 and 22 years. Moreover, few gender differences exist in the process, timing, and pattern/direction of identity development. The domains in which gender differences tend to be found are those of sexuality and family roles, which are likely to hold greater salience for women than for men. Further with respect to developmental patterns, the fundamental developmental hypothesis of the identity status model assumes a decrease in diffusion and foreclosure and an increase in achievement during the course of development. However, comprehensive reviews of the literature (Archer, 1989a; Kroger et al., 2010) have consistently pointed out that, although developmental shifts are largely progressive, regressions do occur.

Kroger et al. (2010) examined the stability (or change) of developmental patterns of identity status during adolescence and young adulthood through meta-analysis of 124 studies published between 1966 and 2005. Results from 11 longitudinal studies showed that the mean proportion of adolescents making progressive identity status changes was 36%, compared with 15% who made regressive changes and 49% who remained stable. Cross-sectional studies indicated that the mean proportion of moratorium individuals rose steadily to age 19 years and declined thereafter, while the mean proportion of identity achievers rose between late adolescence and young adulthood; foreclosure and diffusion statuses declined over the high school years, but fluctuated throughout late adolescence and young adulthood.

Together, these reviews suggest that, although there is a general tendency for individuals' identity statuses to progress from diffusion to foreclosure, to moratorium, and finally to achieved identity, the trajectory of identity development is nonlinear. The exploration-commitment processes underlying the identity statuses are lifelong.

Finally, identifying the correlates of the choice of developmental pathways has been a research interest of scholars for a long time. As early as 1958, Hartmann conjectured that those who attain more adaptive identity statuses would tend to function better in educational, personal, and social domains. Such an insightful supposition has long been empirically supported. More than three decades ago, Marcia's (1980) extensive review of the identity literature showed that identity achievement (and moratorium to a lesser extent) tended to be associated with psychological variables commonly perceived to be desirable, whereas identity diffusion (and foreclosure to a lesser degree) tended to be associated with psychological variables normally deemed to be undesirable. Throughout the years, reviews of a similar nature focusing on different variables have reached the same conclusion – that identity achievement carries the most adaptive value, whereas identity diffusion is the most detrimental to related aspects of psychological functioning, learning, and development, with moratorium being the second most beneficial and foreclosure being the second most damaging (e.g., Hoegh and Bourgeois, 2002).

Conclusions, Limitations, and Implications

This article has demonstrated that there has been much theorizing and empirical testing concerning Erikson's construct of psychosocial development and its companion notion of identity status conceived by Marcia. After reading

what has been presented, one could naturally reach the conclusion that Erikson is not passé; on the contrary, Erikson is very much in fashion. More specifically, the literature reviewed should justify a firm response to each of three fundamental concerns raised by Sorell and Montgomery (2001). First, despite the historical and sociocultural context in which Erikson's theory was constructed, the theory is highly relevant today and perhaps will be for a long time into the future. Second, the popular criticism that the relationship between biological maturation and psychosocial development is merely elaborated from infancy through adolescence is not well grounded, the reason being that Erikson's theory has been shown to take a strong interactionist view of the entire human life span. From the very start, Erikson (1959) maintained that self and society must operate jointly to foster psychosocial development. Finally, although gender differences do exist in aspects of psychosocial development, this does not detract from the fact that Erikson's theory serves both genders. At the very least, empirical findings from studies of both Erikson's stages and Marcia's identity statuses so far have shown more evidence of similarities across genders than of differences.

Limitations

Notwithstanding the above, it should be recognized that scholarship concerning Erikson's theory is far from adequate relative to the value of the theory. A number of limitations exist in the current literature. Most obviously, compared with research on Marcia's identity statuses, research on Erikson's stages is far from being sufficient and systematic. The second limitation concerns the narrow range of research populations covered in almost all lines of investigation. For example, the existing research on the correlates of Erikson's stages among senior adults has, thus far, been conducted exclusively in the United States. Third, the existing research suffers from a severe lack of methodological rigor, most apparently manifested in the lack of adequate control for confounding factors that either moderate or mediate the variables under investigation, the lack of longitudinal investigations, and the lack of intervention studies. A final limitation is that very few studies reported effect sizes of their findings. As much as possible, future empirical research should aim to overcome the aforementioned and other limitations in the existing research. To substantiate the various theoretical claims, comprehensive, systematic, and well-controlled experimental longitudinal investigations must be undertaken in a wide range of populations internationally. Likewise, sound theorizing concerning the work of Erikson and Marcia is highly contingent upon an intimate internal dialogue among scholars.

Practical Implications

Regardless of the said limitations, the existing literature has practical implications for education and beyond. The theoretical argument that psychosocial development results from the interaction between individuals and their environments has long been supported by abundant empirical evidence. Given this, it is reasonable to believe that psychosocial development can be taught. If so, fostering positive psychosocial development either through direct interventions or by developing the attributes of the correlates of the psychosocial development construct (or identity statuses) would make very good sense, be that in academic or in nonacademic settings.

Appendix: Key Measures of the Eriksonian Stages and Identity Statuses

Year	*Author*	*Inventory title*
1964	Rasmussen	Ego Identity Scale
1966	Marcia	Identity Status Interview

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes
Palo Alto and Berlin
June 2001

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser–Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

Erotic Capital

Catherine Hakim, Civitas, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Erotic capital is a combination of physical and social attractiveness. It is the fourth personal asset, alongside economic, social, and human capital. Erotic capital delivers social benefits throughout life, illustrated by gains of 15% extra votes for attractive candidates in elections. It has economic value, delivering earnings mark-ups of between 10 and 20% on average (17% for men and 12% for women). Attractive people gain more friends, lovers, spouses, and sexual experience. They are more persuasive, can sell more goods, services, and policies, are more likely to be perceived as honest and competent, and are treated accordingly. Social, economic, and technological changes are driving the rising social salience and economic value of erotic capital in the twenty-first century.

Erotic capital is a new concept in social science, a label for the personal asset of physical and social attractiveness that has increasing importance in the twenty-first century, and that offers substantial social benefits and economic value to those who choose to develop and exploit it.

Bourdieu's well-known classification of economic, social, and cultural (or human) capital developed for analyses of twentieth-century society is now expanded to include erotic capital as the fourth personal asset in the twenty-first century. Like human/cultural capital and social capital, erotic capital can be exchanged for money and vice versa. Unlike cultural/human and social capital, erotic capital is more randomly distributed by genetic good fortune rather than predicted by parental wealth. Beautiful children can be born into the poorest families, giving them opportunities for upward social mobility. Wealthy parents may have ugly offspring. This socially unpredictable and uncontrollable character of physical attractiveness gives it a 'dangerous' maverick character that has led to it being belittled as superficial and worthless in some cultures. But as Webster and Driskell (1983) recognized in an early paper, beauty confers status, so sociological theory cannot ignore it. New research shows that the economic value of erotic capital is now equal to the value of human capital in affluent societies – so this is not a trivial factor.

By the first decade of the twenty-first century, several writers working independently on sexuality recognized, around the same time, that physical attractiveness and sex appeal have serious value in sexual markets. Seeking a more theoretical term for sex appeal, they adopted various labels: sexual capital (Martin and George, 2006), erotic capital (Green, 2008), and erotic power (Hakim, 2012). These scholars were studying sexual markets, both heterosexual and gay, so the term *sexual capital* is more appropriate for this narrow context. The term *erotic capital* was adopted by Hakim, again working independently, to denote a broader combination of physical and social attractiveness that has value in all spheres of public and private life, including the labor market and politics. Hakim presented the most fully developed concept and theory of erotic capital, synthesized the widest range of research evidence, and discussed the problems of measurement and research methodology for this personal asset (Hakim, 2010, 2011). It is her theory that informs this review essay and that has been most widely taken up by other social scientists.

Defining Erotic Capital

Erotic capital is multifaceted. Beauty is clearly a central element, although there are cultural and temporal variations in ideas about what constitutes beauty. In Papua New Guinea, it is men who paint their faces with dazzlingly colorful patterns, but in the West it is the women who paint their faces. Some African societies admire women with large voluptuous bodies. In Western Europe, fashion models can be tall and stick-thin to the point of being anorexic. In previous centuries, women with small eyes and tiny rosebud mouths were considered delicately beautiful. The modern emphasis on photogenic features means that men and women with large eyes and mouths and 'sculptured' faces are prioritized. Studies show that symmetry, an even skin tone, and conventionality contribute to attractiveness. It is, in part, an achieved characteristic, as illustrated by the French concept of the *belle laide* or *beau laid*, an ugly woman or man who becomes attractive through presentational skills. Great beauty is always in short supply and is therefore universally valorized.

A second element is sexual attractiveness, which can be quite separate from classic beauty. To some extent, beauty is about facial attractiveness, while sex appeal is about a sexy body. However, sex appeal can also stem from personality and style, expressions of femininity or masculinity, and a characteristic of social interaction. Beauty tends to be static, hence is easily captured in a photo. Sexual attractiveness is about the way someone moves, talks, and behaves, so it can only be captured on film. Sex appeal is often linked to youth and can fade rapidly with age. The variation in personal tastes also means there is no universal ideal. Some men prefer women who are small and petite, while others prefer tall and elegant women. Some women prefer men with well-developed muscles and strong athletic bodies, while others prefer a slender, elegant appearance. Despite this variation in tastes, sex appeal is in short supply and is therefore valorized.

A third element of erotic capital is social: grace, charm, social skills in interaction, the ability to make people like you, feel at ease and happy, want to know you and, perhaps, desire you. Flirtatious skills can be learnt, but again are not universal. Some people in positions of power ooze charm and charisma; others have none at all. Some men and women are skilled at discreet flirtation in all contexts; others are incapable.

A fourth element is liveliness, a mixture of physical fitness, energy, and good humor. People who have a lot of life in them can be hugely attractive to others, as illustrated by people who are 'the life and soul of the party.' In most cultures, liveliness is displayed in dancing skills or sporting activities.

The fifth element concerns techniques of social presentation: style of dress, face-painting, tattoos, perfume, jewelry or other adornments, hairstyles, and the various accessories that people carry or wear to announce their social status and style to the world. Heads of state dress for public functions to emphasize their power and authority. Ordinary people going to a party or other social event dress to make themselves attractive as well as to announce their social status and wealth to any strangers they meet or to make style statements. The relative emphasis on sexy attire or social status statements depends on the venue and event. People who are skilled at social presentation appropriate to the social event are more attractive than people who look like homeless vagrants.

The sixth element is sexuality itself: sexual competence, erotic imagination, playfulness, and everything else that makes for a sexually satisfying partner. Whether or not someone is a good lover is known only to their partners, and national sex surveys provide no information on levels of sexual competence. It seems reasonable to assume that sexual skill is not a universal attribute, even among adults, and extreme competence is a minority asset. This last factor usually applies only in private, intimate relationships, whereas the first five exert their influence in all social interaction, visibly or invisibly, at the conscious or (more often) subconscious level.

For men as well as women, all six elements contribute to someone's erotic capital, although one or two elements may dominate. The value of erotic capital can also depend on someone's occupation, which may or may not valorize it. Erotic capital is generally of most value in contexts where there is an audience, where there is a need to persuade or sell, and where people are on public display in some way. The social and economic value of erotic capital is highlighted in occupations in the entertainment and hospitality industries, but is also significant in professional and managerial occupations. Erotic capital helps to sell products, services, ideas, and policies.

Erotic capital is thus a combination of aesthetic, visual, physical, social, and sexual attractiveness to other members of the society, and especially to members of the opposite sex, in all social contexts. In some cultures, fertility would be an additional element of women's greater erotic capital. Erotic capital is partly genetic but is not fixed at birth. Almost every element requires skills that can be learned and developed. The most obvious example is people who change the color of their hair to stand out and be more attractive, for example, by changing from brown to blonde. An ugly person can become attractive through the use of flattering hairstyles, cosmetics, physical fitness, flattering colors and styles of clothes, cosmetic surgery, and developing charming manners. Women generally have more of it than men, even in cultures where fertility is not an integral element, and they deploy it more actively.

Studies show that physical and social attractiveness are too closely interlinked to be disentangled, even though most studies try to tease out the impact of each of the six elements separately. The most notable finding from an ingenious study in Argentina was that attractiveness had the same impact on social interaction whether employers met workers face-to-face, saw only a photo of the worker, or never saw anyone at all and only spoke to people on the phone. As usual, attractiveness raised assessments of ability, success, and earnings by between 13 and 17% (Mobius and Rosenblat, 2006; Hakim, 2011: pp. 170–171).

The Increasing Importance of Erotic Capital in the Twenty-First Century

Erotic capital is of growing importance in the twenty-first century, and in knowledge economies, for three reasons.

First, the workplace has changed, so social skills and charm are crucial now in many jobs in modern economies. The shift from manual jobs in manufacturing industries to white-collar and service sector work makes erotic capital more important because good social relationships, and smooth social interaction, are crucial in the workplace. For example, even in academia, where the focus is on specialist knowledge, professors who are attractive are judged more competent by their students (Hamermesh, 2011).

Second, as people and societies become more affluent, they spend more on luxuries, including beauty, courtesy, charming good manners, nice clothes, pleasant service, and good looks. People who offer erotic capital in addition to any other talents will thus be more successful.

Third, we are all more visible now due to digital photography and the Internet. Even private individuals become exposed through their photos on Facebook and other social networking sites, and images of celebrities and politicians proliferate in the media. A good appearance matters more now, both in private and public life.

Currently, the emphasis is on educational qualifications as the route to success in life, especially among academics. However, recent research shows that physical and social attractiveness is *equally important* to qualifications for success in life, on average. For some individuals, such as models and film stars, it can be much *more important* and the source of great wealth.

The increasing emphasis on visual culture, and on erotic capital, in developed economies has led some commentators to criticize what they regard as the sexualization of society. This is most common in the Anglo-Saxon Puritan cultures of North America and Britain, where the value of erotic capital (and related luxuries and entertainments, such as sumptuous clothing, music, and dancing) has been denied, historically. Some feminist writers are now extending this Puritan tradition of denigrating appearance as trivial, superficial, and worthless (Jeffreys, 2005; Rhode, 2010). Almost invariably these critical writings assume that the new emphasis on attractiveness affects women exclusively, or primarily. For example, they point to the fact that women spend money (or are 'forced' to spend money) on cosmetics. This overlooks the fact that men's rising investment in erotic capital takes different forms – such as committing to regular exercise in order to maintain fitness and build an athletic body (Thompson and Cafri, 2007), using nutritional supplements to enhance their appearance and stamina, using products to

avoid male-pattern baldness and maintain a healthy head of hair, spending money on extensive body tattoos, and even cosmetic surgery – as well as keeping slim, having good haircuts, and buying flattering clothing, just like women.

Social anthropological evidence, for example, from African tribes, shows that men and women have always invested time, money, and effort in looking good. In modern societies, there is simply a greater choice of styles and more diversity than in societies where self-presentation was dictated by tribal affiliation, sex, marital status, age, and social roles.

The Distribution of Erotic Capital

Only a few North American surveys provide information on national distributions of attractiveness. Most of them use the five-point scale shown in Table 1. On this scale, the majority of men and women are graded 'average' in looks, between half and two-thirds. A quarter to one-third are graded above average for their age, including tiny minorities of exceptionally handsome people. Around 1 in 10 are judged below average for their age. In these surveys, and most other studies, women are assessed as better-looking than men, probably because they expend more effort on grooming.

The distribution observed in North America may be idiosyncratic rather than universal. For example, in Shanghai, Chinese people are reluctant to grade anyone as below average (Hamermesh et al., 2002). So almost all women are assessed as average (2/3), above average (29%), or exceptionally beautiful (6%).

The Economic Value of Erotic Capital

Hatfield and Sprecher (1986) produced the first research synthesis on the diverse social and economic benefits of attractiveness in everyday life. The studies they review attest to the impact of erotic capital in all social interaction, but most are relatively small scale, reflecting the dispersed and exploratory nature of the field in the twentieth century. Hakim (2010, 2011) and Hamermesh (2011) present systematic reviews of the recent research evidence on the advantages of attractiveness. Hamermesh reviews economic studies in a textbook designed to explain how economists measure discrimination. Hakim synthesizes research in sociology, social psychology, economics, politics, social anthropology, and history to demonstrate the social and economic value of erotic capital in all contexts and all cultures.

From the American studies he reviews (most of them his own) Hamermesh concludes (2011: pp. 45, 50) that the average economic gain for an above-average attractive person compared to an unattractive person is 15%, all else equal, but the beauty premium is slightly higher for men at 17% than for women at 12%, on average.

Hakim concludes that someone with high erotic capital gains an average financial mark-up of between 10 and 20%, as compared with someone with below-average appearance. While this may seem a small addition, she notes that this can add up to a substantial cumulative gain over a lifetime, given that any small marginal advantage can deliver a large gain in 'winner-take-all' competitions for jobs or business opportunities, and in other situations where there are numerous candidates but only one winner. With the impact of globalization, and the trend toward larger multinational companies, the financial rewards for top jobs have increased, and so has the competition for them. As a result, the importance and potential benefits of any marginal advantage in personal assets, including erotic capital, are clearly increasing in the higher echelons of professional and management jobs. This may explain why cosmetic surgery companies report a steady increase in male customers in the twenty-first century, even during recessions.

In addition, exceptionally attractive men and women can become multimillionaires by exploiting their erotic capital alone. The most obvious examples are photographic models such as Kate Moss, Elle Macpherson, and Gisele Bundchen. Many film stars also benefit substantially from investing in their appearance and from fronting advertisements for luxury goods, including watches. One of the most beautiful film stars, Elizabeth Taylor, is said to have earned more from promoting her celebrity perfumes than from her lifetime earnings as an actor. Similarly, the footballer David Beckham is said to earn more, globally, from appearing in advertisements than from his main career as an athlete.

Quantitative and qualitative studies, case studies, and laboratory experiments are consistent in showing a slightly higher average return to erotic capital for men than for women. Typically, this is in earnings or adult incomes attained, but studies often show a similar sex differential for promotion and other rewards in the labor market. The most startling example

Table 1 Distribution of looks in the United States and Canada, 1970s

	American studies				*Canadian study*	
	1971		*1977*		*1977–81*	
	M	*F*	*M*	*F*	*M*	*F*
1. Strikingly beautiful or handsome	3	3	1	2	2	2
2. Above average (good looking)	24	28	27	30	32	32
3. Average for age	60	52	60	52	58	57
4. Below average for age (quite plain)	11	15	11	14	7	8
5. Homely	2	2	1	2	1	1
$N = 100\%$	864	1194	959	539	3804	5464

Source: Table 2 in Hamermesh, D., Biddle, J., 1994. Beauty and the labor market. American Economic Review 84, 1174–1194.

of this sex differential is found in the incomes of Hollywood film stars: top male stars can earn double the annual incomes of top female stars, according to regular *Forbes* estimates.

As yet, explanations for the sex differential in returns to erotic capital are purely speculative. One possibility is that this is yet another reflection of women's failure to exploit their advantages, their failure to negotiate and bargain for a better deal, in both private and public life (Hakim, 2011: pp. 200–205). Another is that it is a straight reflection of discrimination against women. This is the explanation adopted by Rhode (2010) and Hamermesh (2011); both assume that the returns to attractiveness are entirely unjustified and discriminatory. The third possibility is that the differential is restricted to Puritan Western cultures, where the value of beauty and sexuality have always been denied, as Hakim pointed out (Hakim, 2011: pp. 63–86). Research indicates that women's erotic capital is more highly rewarded outside the Puritan Anglo-Saxon countries where the bulk of recent studies have been carried out. For example in Shanghai, the economic returns to female attractiveness are higher than in the United States. They are at least equal to the returns for men and much higher for very attractive women (Hamermesh et al., 2002; Hamermesh, 2011: pp. 138–139). There is consistent evidence from many other sources that most cultures value attractiveness more positively than in America and Britain (Hakim, 2011: pp. 135–162).

Some studies have sought to compare the returns to attractiveness with the returns to educational qualifications (as a proxy for human capital more broadly). The best studies show that attractiveness, qualifications, and self-confidence deliver equal gains in income once the impact of intelligence and ability has been separated out (Judge et al., 2009; Hakim, 2011: p. 170). It appears that many studies greatly overstate the impact of educational qualifications on incomes because they do not separate out the influence of IQ, which is time consuming to measure. These results also show that the economic value of erotic capital is not due simply to any consequential gain in self-confidence, as this has a separate, equal impact of its own on incomes.

The returns to erotic capital appear to be larger in the higher echelons of the occupational ladder, where performance assessments can become subjective. In any event, attractiveness offers additional benefits to the highly qualified. Studies of the graduates of top law schools, and MBA graduates, found that attractive men and women earn 10–12% more than the unattractive ones, especially after several years on the job, when their talents and performance have been proven. The largest corporations tend to have better-looking CEOs than smaller companies. More generally, employing beautiful people has been shown to raise companies' sales and profits (Hamermesh, 2011).

The Social and Political Value of Erotic Capital

The first decade of the twenty-first century was the 'lift-off' period for concerted social science attention to the social, sexual, political, and economic benefits of attractiveness, with many new studies in all disciplines. Several reviews of the evidence were published, some of them focusing on female beauty and sex appeal, apparently geared toward the new gender studies courses. In line with the Western world's emphasis on facial beauty, and the research opportunities opened up by digital photography, many studies had an initial focus on facial beauty and body shape, but they usually went wider to tap erotic capital more broadly (Marwick, 2004; Hakim, 2011; Hamermesh, 2011). However, most reviews focus on adult lives, ignoring social processes during childhood.

The benefits of attractiveness are seen from birth onward. Beautiful babies and children attract more attention, assistance, social interaction, tolerance, and gifts – from complete strangers as well as friends and family. As a result, attractive children develop their cognitive and social skills faster, just as tall children benefit from being treated as older than their age. They are given more opportunities and have a smoother path in life.

These benefits continue in adult life. Attractive people are perceived as more intelligent, competent, and honest, and treated accordingly. They are given more support, cooperation, and assistance of every kind, by complete strangers as well as teachers, colleagues, acquaintances, and friends. For example, men and women who are attractive, well-groomed, and well-dressed are less likely to be arrested and less likely to be found guilty – unless the offense involved exploiting their good looks. Attractive men and women get loans more easily, win bigger contributions to charity, are more readily welcomed into social groups, and attract more good-looking and/or wealthy spouses.

As Aristotle once noted, beauty is the best letter of introduction. Maupassant's 1885 novel *Bel Ami* (*Beautiful Friend*) describes how a poor but handsome young man exploits his erotic capital for dramatic upward social mobility in nineteenth-century France, finally marrying into a wealthy family. In China today, handsome young men and women set out similar aspirations on dating websites. Yet young women who do the same in the Western world can be denigrated as 'gold-diggers' rather than recognized as exploiting their talents in exactly the same way as do men. It appears that there is an unstated double standard when it comes to exploiting erotic capital: men can do it; women should not do it at men's expense.

Attractive, charming, and charismatic men and women stand out from a young age, are remembered positively, so find it easier to develop their social as well as human capital. They develop more positive personalities and become more likable and acquire more friends and contacts. The association between intelligence and attractiveness is small at 0.10, but it is unmistakable. It may be a recent development.

The social benefits of being attractive explain why such people are more persuasive and can sell more goods, services, ideas, and policies. Research shows that people prefer to interact with, or buy from, an attractive person, even when they are aware it makes no difference to the transaction. Beauty is a good in itself and is a desirable luxury. All these results apply equally to men and women and are not affected by the sex of the assessor (Hakim, 2011).

Political studies provide the best alternative to economics for measuring the social impact, or value, of erotic capital. Instead of measuring additional income or earnings, political

scientists measure the additional votes won by above-average attractive people compared with those who are below average in appearance (Berggren et al., 2010; Hakim, 2011).

Studies show that attractive candidates win 15% extra votes on average. This advantage applies equally to male and female candidates. A good appearance has the strongest impact on votes for right-wing political parties and for candidates who are newcomers to the political scene, those who have no established track record. These patterns are repeated in nonpolitical elections, for example, voting for candidates onto committees or other roles in professional organizations and representative bodies (Hamermesh, 2011). Young people especially benefit from the extra goodwill accorded to attractive newcomers.

Overall, studies of the social and economic benefits of erotic capital are highly consistent. There is a +15% average benefit; the benefit is greatest for relative strangers, for whom there is little other information; and the benefits are generally larger for men than for women, despite the fact that women tend to score higher on erotic capital. The social benefits are substantial enough to justify the economic returns to attractiveness on grounds of improved productivity.

The Value of Erotic Capital in Intimate Relationships

It is well established that attractive men and women have a smoother path in dating, mating and marriage markets, and tend to marry younger. Attractive women tend to marry spouses with greater economic, social, and human capital (Feingold, 1990; Baumeister and Vohs, 2004; Todd et al., 2007; Hamermesh, 2011).

It is notable that national sex surveys and studies of sexuality carried out in the twentieth century do not even consider the impact of attractiveness and sex appeal on sexual activity, let alone attempt to measure it. The key exception was the first ever national survey of sexuality carried out in Sweden in 1967 by a sociologist, Hans Zetterberg, who was aware of the secret status ranking of sex appeal and sought to measure it and study its impact. Unfortunately, he published no survey results on this topic.

However, Zetterberg's 1967 Swedish survey inspired an entire research program in Finland, including a series of sex surveys in Finland and other Baltic states. Here, they did collect data on sex appeal and publish results on its impact on sexual behavior (Kontula, 2009: pp. 121–123). They confirmed the results of other studies by social psychologists and sociologists showing that attractive people have an earlier sexual debut, acquire wider experience, have more affairs, and (in Europe at least) have more partners than men and women who lack sex appeal. They also express greater satisfaction with their sex lives.

Studies of gay communities in North America show that sexual capital is of even greater importance than in heterosexual relationships and meet markets. High standards of sex appeal and physical fitness are underlined in gay meeting places such as bathhouses where men parade naked, and in bars and clubs where the right look, the right style of body and clothes can be crucial to acceptance, social interaction, and desire. Men who score low on sexual capital, due to age or lack of fitness may be ostracized, have reduced chances of sexual hook-ups, can have little or no control over the choice of partner, and may feel obliged to accept less safe sexual practices imposed by the more attractive partner. In situations where there is little or no scope for the exchange of money and sexual capital, physical attractiveness may become the dominant factor in relationships and sexual status rankings.

Studies of men and women who sell sexual services and erotic entertainment (such as lapdancing and stripping) invariably show a substantial mark-up in prices and incomes for the most attractive entertainers. These studies confirm that facial beauty alone is less important than the complete package of erotic capital, including liveliness and social skills. Young beautiful lapdancers who are glacial in manner make far less money than less beautiful women who have more positive personalities and good social skills. The high fees achieved by some men and women who sell sexual services (Hakim, 2011) demonstrate the very high full economic value of erotic capital in the round (all six elements).

Measuring Erotic Capital and Research Methods

As yet, no one has tried to measure erotic capital in the round. Studies typically focus on particular elements, such as facial beauty, body shape, or dress style, but inevitably capture the wider impact of social skills as well as physical looks, as most scholars recognize (Hakim, 2011).

Nationally representative surveys using face-to-face interviews have asked interviewers to grade respondents' appearance on the five-point scale shown in **Table 1**. Other studies employ three to five judges, male and female, of diverse ages, to grade the attractiveness of photos or videos in order to produce an average score for each image, before using the images in laboratory experiments or other studies.

Analyses show an astonishing degree of agreement and consistency in rankings, irrespective of the sex of the grader, respondent, or image. There is consistency in rankings even across cultures and races (Hakim, 2011).

People who are scored above average when young tend to be seen the same way decades later, indicating consistency across the life cycle as well. Validity and reliability of assessments do not appear to be a problem. Most people can distinguish between their own personal tastes and impersonal general assessments of someone's attractiveness within their society. So beauty may be in the eye of the beholder in private lives, but most people can recognize an Aphrodite or Adonis as exceptional within their society. Even people who prefer blondes can see that Elizabeth Taylor and Pierce Brosnan were exceptionally attractive in their prime.

Social psychologists have yet to develop a reliable measure of social skills or social intelligence (as they label it), but methodological work is slowly bearing fruit. Similarly, although Hochschild's (1983/2003) concept of emotional labor has proven popular, there is no agreed method for measuring it properly. However, in everyday life, we have no difficulty distinguishing people who are likable and charming from those who are clumsy, rude, or abrasive.

The advent of digital photography opened up a whole new research field for analyzing facial beauty, body shape, and styles of movement using IT to manipulate photos and videos to test what specific features of people are perceived as attractive or unattractive, such as the ideal hip-to-waist ratio. This new field of research is yielding important new discoveries (such as the importance of symmetrical features), with more to come.

Computer-based laboratory experiments use IT to manipulate the appearance of photos or videos of confederates to allow researchers to measure how each precise alteration affects responses, in terms of cooperation, generosity, and liking, for example, in variants of the Prisoner's Dilemma game.

Some studies have hired exceptionally handsome and beautiful actors to play a role in laboratory experiments that mimic natural social settings, to assess whether and how their good looks alters the results obtained from studies using invisible or ordinary-looking actors.

In sum, researchers are being extremely inventive in devising new types of study that measure the overall attractiveness of individuals; identify the key elements of attractiveness; or test for the impact of attractiveness on the responses, attitudes, perceptions, and social behavior of viewers. The latest studies have started to assess the benefits of attractiveness *relative* to other assets such as human capital or intelligence (Judge et al., 2009).

Studies normally differentiate between attractiveness (erotic capital), height, and body weight (using body mass index (BMI) as the standard measure). It is well established that there are separate effects of being tall (rather than short), being slim or normal weight (versus obese), and being attractive (versus ugly). These three aspects of appearance all affect social interaction and perceptions, sometimes with different effects for men and women. For example, obesity in women is judged more harshly than in men. Tallness is an advantage for men and women, but not beyond a certain point, when it becomes anomalous or dysfunctional. The research summarized here concerns the effects of attractiveness, excluding the effects of BMI or height. It is notable that the legal cases discussed by Rhode (2010) concern obesity (and the overweight) more often than attractiveness. Like tallness, obesity quickly becomes dysfunctional, for example, when extremely tall or fat people cannot fit into car or airline seats. Ugliness is rarely dysfunctional in this way, even if it limits access to certain occupations.

Directions for Future Research

Research on the social, political, economic, and sexual effects of attractiveness is a new and growing field, with contributions from sociology, social psychology, economics, political science, historians, and IT specialists. Lawyers have also become involved, typically assuming that attractiveness is worthless and prompts unlawful discrimination (Rhode, 2010). The only theoretical perspective that encompasses all disciplines, methods, and social contexts is Hakim's (2010, 2011) theory of erotic capital. Further methodological developments and discoveries can be expected in the next two to three decades. One continuing barrier is the cross-disciplinary character of the research field, with scholars in one discipline failing to pick up and incorporate relevant work being done in another discipline. There is, as usual, a fairly large divide between experimental computer-based and laboratory studies, and research on real-life settings and actors, such as studies of the careers of law school and MBA graduates. Contrary to the usual pattern, real-life studies often reveal larger (long-term) impacts of erotic capital than laboratory experiments. This is another indication that erotic capital in the round has wider effects than any single element.

There is growing recognition of the importance of erotic capital in many fields of activity where appearance may initially seem irrelevant, such as sport (Guttman, 1996) and politics (Berggren et al., 2010), as well as the more obvious fields of advertising (Reichert, 2003) and sexual markets (Feingold, 1990; Martin and George, 2006; Hakim, 2011, 2012). There is also increasing attention to the role of physical attractiveness in men's lives, especially in gay sexual communities (Thompson and Cafri, 2007; Green, 2008), providing a welcome balance to the excessive focus on women. We can anticipate many more case studies of the role of erotic capital in particular fields and social contexts; its role in dating, sexual and marriage markets; and more research to test for the *relative* importance of social, human, and erotic capital alongside cognitive ability (IQ), a factor which is so often overlooked in social science research.

Research on Internet dating and speed-dating events, and Facebook-based analyses, provide a fruitful combination of laboratory-style controls and real-life behaviors (Todd et al., 2007). Some of the most interesting future research is likely to come from these studies, which often combine disciplinary perspectives and skills to best effect.

This article is reproduced from the previous edition, volume 7, pp. 4739–4744, © 2001, Elsevier Ltd., with an updated Bibliography section supplied by the Editor.

Abstract

This article discusses the assumptions that underlie statistical procedures and how violations of these assumptions can affect the properties of a procedure. Both theoretical and simulation methods are discussed for assessing the sensitivity of properties of statistical procedures to violations of their assumptions. The example of the *t*-test is considered in detail.

Each statistical procedure rests upon a collection of assumptions for its validity. For example, many statistical procedures assume that a data set consists of a collection of independent observations. A large number of these same procedures also assume that the observations all have the same distribution. Each of these assumptions, as well as any others that a procedure assumes, may or may not be reasonable in a given application. If one or more of the assumptions justifying a procedure fail to hold, the statistical properties of the procedure may be different than they would be if the assumptions hold. This article discusses ways to assess the sensitivity of a statistical procedure to violations of its assumptions.

Introduction

The development of almost every statistical procedure is accompanied by a list of properties possessed by the procedure under some specified statistical assumptions. For example, the *t*-test is a uniformly most powerful unbiased level α test if one assumes that the data $X_1, \ldots, X_n$ comprise a sample of independent random variables with common normal distribution. Of course, one can perform a *t*-test with data $X_1, \ldots, X_n$ regardless of whether one makes some or all of the assumptions. One cannot expect the associated properties to hold, however, if one does not believe the assumptions. If one has reason to believe (or fear) that one or more of the assumptions used to justify a statistical procedure fail to hold, then one should be concerned with how sensitive the properties are to the assumptions. For example, suppose that the observations $X_1, \ldots, X_n$ have some distribution other than normal. How much does that affect the probability of type I error when I use the level α *t*-test? How much does it affect the power of the test at important alternatives? This article will not attempt to answer all of the questions of this sort. Rather, this article describes general ways to assess the sensitivity of statistical procedures to specific violations of their assumptions. An excellent discussion of the role of assumptions in statistical models was initiated by Box (1980).

Related to the question of sensitivity is the question of diagnosis. That is, can one tell whether or not the data suggest that certain assumptions are indeed violated? There are several statistical methods that have been developed to diagnose violations of assumptions of the linear regression model. Some of these are discussed in Linear Hypothesis: Regression (Graphics).

For a given statistical procedure, one first needs to be aware of what assumptions justify the procedure. Then one needs to decide which aspects of the procedure and which assumptions the sensitivity of which one wishes to assess. One needs to decide which violations of those assumptions one is willing to contemplate and finally how one wishes to measure the sensitivity. Each of these issues is examined in a detailed study of one statistical procedure in the section 'The *t*-test'.

Theoretical results concerning sensitivity can be difficult to derive, even for the most elementary types of violations. Hotelling (1961) and Efron (1969) analyze the effects of some specific types of violations on the distribution of the *t* statistic. Box (1953) discusses the effects of violations of assumptions on tests concerning variances.

The *t*-test

Since the *t*-test is such a popular statistical procedure, let us first consider violations of its assumptions. The assumptions for the validity of the *t*-test are that the data comprise a sample of independent random variables, all with the same normal distribution. Specifically, there are three key assumptions:

1. the observations are independent;
2. the observations all have the same distribution; and
3. each observation has a normal distribution.

There are many ways in which these assumptions can be violated. For example, the observations might be dependent. (*See* Time Series: General for discussion of one type of model of dependence between observations.) The observations might have different distributions. Alternatively, some or all the observations might have distributions other than normal. Finally, it is possible that more than one assumption is violated. For example, each observation could have its own distribution, none of which is normal, and they could be dependent.

The most crucial properties of a test procedure are its size and power. These can be measured from the distribution of the test statistic given a set of assumptions about the data. For example, consider a test of the null hypothesis that the mean μ of a sample of random variables is 0. If one were interested in measuring the sensitivity to the assumption that the data are normal, and if one contemplates the possibility that a linear function $a(X-b)$ of each observation X has a Cauchy distribution, then one must reinterpret μ to be something other than the mean (e.g., the median, b). The power of the test can then be written as a function of $a\mu$.

Theoretical Results

Clearly, it is not reasonable to expect to find theoretical results that handle every possible departure from the assumptions. For some violations, it is possible to determine analytically how sensitive a procedure will be. For example, suppose that the observations $X_1,\ldots, X_n$ have normal distribution with mean μ and common variance σ^2, but that they have common correlation ρ. And suppose that one wishes to perform a t-test of the null hypothesis that the mean of the distribution is μ_0. The t statistic has the form

$$T = \frac{\overline{X} - \mu_0}{\sqrt{S^2/n}} \qquad [1]$$

where $\overline{X}$ is the sample average and

$$S^2 = \frac{1}{n-1}\sum_{i=1}^{n}\left(X_i - \overline{X}\right)^2 \qquad [2]$$

Under the usual assumptions for the t-test, if $\mu = \mu_0$, then T has a t distribution with $n-1$ degrees of freedom. In the case of common correlation, it is possible to show that the random variable $U = T/\sqrt{1 + n\rho/(1-\rho)}$ has t distribution with $n-1$ degrees of freedom. If ρ is greater than 0, the distribution of T will be more spread out than the nominal t distribution if $\mu = \mu_0$. This will have the effect of making the size of the t-test larger than its nominal value. For example, if $\rho = 0.05$ and $n = 10$ and one uses a test with nominal size 0.05; the actual size is 0.10. If the null hypothesis is false and $\mu \neq \mu_0$, then U has noncentral t distribution with $n-1$ degrees of freedom and noncentrality parameter $\mu\sqrt{n/[1+(n-1)\rho]}$. The effect of this on the power of the test is not so obvious, but it is not as dramatic as the effect on the size.

For other violations, one can attempt to reason qualitatively what the effect will be. For example, suppose that the observations $X_1, \ldots, X_n$ come from a distribution with heavier tails than a normal distribution (i.e., observations far from the median occur with high probability). And suppose that one wishes to perform a t-test of the null hypothesis that the median of the distribution is μ_0. Some theoretical results concerning this case have been derived by Benjamini (1983). A heavy-tailed distribution will produce a value $\overline{X}$ with more variability than a normal distribution will. That is, we would expect to see large values of $\left|\overline{X} - \mu_0\right|$ with higher probability from a heavy-tailed distribution than from a normal distribution. But the effect of heavy tails on $\sqrt{S^2/n}$ should be even greater than the effect on $\overline{X}$ because the squaring gives the large deviations $X_i - \overline{X}$ much more prominence. Hence, one expects $|T|$ to be smaller if the data have a distribution with heavy tails than if the data have normal distribution. Not all violations lend themselves to qualitative analysis of this sort, however. And, as Benjamini (1983) points out, an intuitive analysis like this might only hold in special cases, as will be noted later in this article.

When one wishes to focus on a specific collection of possible violations, then one can perform simulations to assess both qualitative and quantitative sensitivity. Simulation has advantages and disadvantages when compared to theoretical analysis. A simulation can be designed to assess the sensitivity of any statistical procedure to any specific collection of violations of its assumptions. However, each simulation analysis assesses only the specific violations for which it was designed and does not tell us how sensitive the procedure is to other, albeit similar, violations. Of course, simulations are generally quick and easy to perform, so one could perform many of them to cover a large number of specific violations. The remainder of this section illustrates the sorts of simulations that one might perform in order to assess the sensitivity of various aspects of t-test to some of the more easily understood violations of assumptions.

Violations of Normality

Suppose that one thinks that the observations are normal with mean μ and variance σ^2, and that one wishes to test the null hypothesis that $\mu = 0$. Suppose that most interest lies in a test with level 0.05 and with the power of the test when $\mu = \sigma$. However, suppose that one is willing to contemplate the possibility that the data come from a distribution that is not normal. If that distribution does not have a mean or does not have a variance, then one will need to reinterpret μ and/or σ. For distributions without a mean, let μ stand for the median. For all distributions, let σ stand for 0.741 times the interquartile range (which happens to be the standard deviation when the data have a normal distribution). Now, one can simulate samples of size n from every distribution that one wishes to consider and compute the probability that $|T| > c$, where c is the 0.975 quantile of the t distribution with $n-1$ degrees of freedom. For distributions with mean (or median) 0, this probability will be the size of the test. For distributions with mean $\mu = \sigma$, this probability will be the power of interest. Table 1 reports the results of several simulations. Each row of the table represents two million simulated samples of size $n = 10$ or $n = 20$ from a distribution that is not normal. The simulated data from the t distribution have three degrees of freedom. The simulated data from the gamma distribution have parameter 2. The σ in the last column is 0.741 times the interquartile range. The 'normal' rows give the theoretical values under the normal distribution assumption. For each sample the statistic t was computed. The table reports the

Table 1 Simulated sizes and powers of the t-test under violations of normality

		Prob. of $\lvert T\rvert > c$	
Distribution	*Sample size (n)*	$\mu = 0$	$\mu = \sigma$
Laplace	10	0.042	0.593
	20	0.046	0.862
Cauchy	10	0.019	0.295
	20	0.020	0.325
t (3 degrees of freedom)	10	0.040	0.619
	20	0.043	0.848
Uniform	10	0.054	0.971
	20	0.052	1.0
Exponential	10	0.099	0.786
	20	0.081	0.997
Gamma (2)	10	0.077	0.838
	20	0.066	0.999
Normal	10	0.05	0.803
	20	0.05	0.989

estimated probability that $|T| > c$ for c equal to the 0.975 quantile of the t distribution with $n-1$ degrees of freedom.

A quick look at the rows of Table 1 corresponding to heavy-tailed distributions (Laplace, Cauchy, t) indicates what we argued earlier. That is, the probability of $|T| > c$ is smaller for these heavy-tailed distributions than for the normal. However, as is common with simulations, one must be careful not to generalize too far. If one had considered level 0.20 tests instead of level 0.05 tests, the results would have been slightly different. For example, with the Laplace distribution, the estimated level is slightly higher than 0.2 with samples of both sizes 10 and 20. This is consistent with the theoretical results of Benjamini (1983).

Violations of Common Distribution

For the assumption that the observations have the same distribution, there are many possible violations. The data might split into two (or a few) groups, each of which has a common distribution. Alternatively, each observation could have its own distribution. Or there might be just one (or a few) observation(s) with distribution different from the others. All of these are possible even if one believes that each of the individual distributions has a normal distribution.

Table 2 gives the results of several simulations. As before, each simulation is based on two million simulated samples of size $n = 10$ or $n = 20$. Each sample consists of n normal random variables with a common mean μ but with either 10% or 50% having a larger standard deviation than the rest. The larger standard deviation is either 2, 5, or 10 times as large as the smaller one. The value of σ in the last column is

$$\sigma = \sqrt{(1-p)\sigma_1^2 + p\sigma_2^2} \qquad [3]$$

where σ_1 is the smaller standard deviation, σ_2 is the larger standard deviation, and p is the proportion of the sample with the larger standard deviation. The 'ratio = 1' rows give the theoretical values under the assumption that the data have a common normal distribution. The table reports the estimated probability that $|T| > c$ for c equal to the 0.975 quantile of the t distribution with $n-1$ degrees of freedom. Note how the size of the test can be significantly lowered by the inclusions of 10% of the observations with a standard deviation 5 or 10 times as large as the rest. The power of the test at $\mu = \sigma$ is not much affected by this type of violation. However, the value of σ/σ_1 increases as the ratio of the two standard deviations increases. If one had calculated the power at a fixed alternative, there would have been a dramatic decrease in power as the ratio of standard deviations increased and as the proportion with the larger standard deviation increased.

Table 2 Simulated sizes and powers of the t-test under violations of common distribution

Ratio of standard deviations	*Sample size*	*Proportion with larger standard deviation*	*Prob. of $\|T\| > c$*	
			$\mu = 0$	$\mu = \sigma$
2	10	0.1	0.047	0.809
	10	0.5	0.046	0.804
	20	0.1	0.048	0.984

	10	0.5	0.033	0.799
	20	0.1	0.015	0.948
	20	0.5	0.045	0.981
1	10	0	0.05	0.803
	20	0	0.05	0.989

Violations of Independence

Violations of the independence assumption are a bit more difficult to think about. There are simple violations such as equal correlation that is not 0. Indeed, this case is the one that lent itself to an analytic solution earlier in this article. Another type of violation of independence is time-series dependence. This means that the amount of dependence between observations depends on the order in which they were observed. Many data sets are collected without recording when the observations were made. This would make it impossible to perform a traditional time series analysis. However, we can still assess the effect of time series dependence on the distribution of a statistic like t, even if one did not record the observation times. For example, suppose that observations arrive in the order $x_1, \ldots, x_n$, regardless of whether or not one knows this to be true. One might consider the possibility that $x_i = \rho x_{i-1} + \varepsilon_i$ for $i = 2, \ldots, n$. Here $\rho \in (-1, 1)$ and $\varepsilon_2, \ldots, \varepsilon_n$ are assumed to be mutually independent with variance $(1-\rho^2)\ \mathrm{Var}(x_1)$. This type of dependence is called autoregressive of order 1. (For more detail on autoregressive dependence, *see* Time Series: ARIMA Methods.)

Table 3 presents the results of several simulations. Each simulated sample has autoregressive dependence of order 1 with a different correlation. Each number in the table is based on 2 000 000 simulated samples. The rows with '$\rho = 0$' give the theoretical values under the assumption that the data are independent. The table reports the estimated probability that $|T| > c$ for c equal to the 0.975 quantile of the t distribution

Table 3 Simulated sizes and powers of the t-test under violations of independence

Sample size (n)	*Correlation (ρ)*	*Prob. of $\|T\| > c$*	
		$\mu = 0$	$\mu = \sigma$
10	0	0.05	0.803
	0.1	0.072	0.792
	0.3	0.138	0.773
	0.5	0.245	0.759
	0.7	0.412	0.761
	0.9	0.672	0.824
20	0	0.05	0.989
	0.1	0.074	0.982
	0.3	0.145	0.962
	0.5	0.256	0.928
	0.7	0.422	0.883
	0.9	0.688	0.864

with $n-1$ degrees of freedom. Even correlation as small as 0.1 has a noticeable effect on the size of the test.

Linear Regression

The assumptions which justify the standard inferences in linear regression are a bit more complicated than those which justify the t-test. In turn, the types of violations of these assumptions are also more complicated. To be specific, consider simple linear regression. The data comprise a set of pairs $(Y_1, x_1),\ldots,(Y_n, x_n)$, and the numbers $x_1,\ldots, x_n$ are considered fixed, known constants. Alternatively, the remainder of the probabilistic statements are to be understood conditional on these values. The assumptions are that

1. the random variables $Y_1,\ldots, Y_n$ are independent,
2. every Y_i has a normal distribution,
3. Var (Y_i) is the same for all i, and
4. there exist numbers β_0 and β_1 such that $E(Y_i) = \beta_0 + \beta_1 x_i$.

This section will briefly discuss violations of these assumptions, but not in as much detail as it did for the one-sample t-test. Failures of independence can come in the same forms that they did for the one-sample t-test. However, there are additional varieties available as well. For example, one might consider the possibility that there is correlation between Y_i and Y_j that depends on how far apart x_i and x_j are. Each Y_i can have a distribution that depends on x_i through more than just its mean and/or variance. Indeed, there are standard methods in regression analysis for diagnosing and dealing with cases in which it appears that Var (Y_i) depends on x_i. The dependence of $E(Y_i)$ and x_i can be very general. It might seem reasonable in some problems to assume that $E(Y_i)$ is a monotone function of x_i, but not always. For more discussion of regression methodology, including diagnosing violations of assumptions, *see* Linear Hypothesis: Regression (Basics) and Linear Hypothesis: Regression (Graphics).

Sensitivity of Bayesian Procedures

Bayesian procedures (*see* Bayesian Statistics), being statistical procedures, are also based upon probabilistic assumptions, and are thereby sensitive to violations of their assumptions. Typically, a Bayesian procedure is based on the same types of assumptions as any other procedure plus additional assumptions about the distributions of any parameters (such as μ and σ^2 in the t-test) that might appear in the statistical model. These latter assumptions are generally part of what is called the prior distribution of the parameters. Sensitivity of Bayesian procedures to violations of all of these assumptions can be assessed in a manner similar to what was done earlier in this article. However, those who use Bayesian procedures to represent subjective beliefs conditional on the observed data would be more interested in assessing sensitivity in a different manner.

For example, suppose that one wants an interval estimate of a parameter μ, and one models data $X_1,\ldots, X_n$ as independent normal random variables with mean μ and variance σ^2. One would also specify a prior distribution for (μ, σ^2). After observing the data values $X_1 = x_1,\ldots, X_n = x_n$, one would then compute the appropriate interval estimate (a, b). Then one could ask what interval would have been computed if one had modeled the data as having a different distribution. For example, suppose $(X_i - \mu)/(0.6745\sigma)$ are modeled as independent with Cauchy distribution. (The factor of 0.6745 makes the interquartile range of X_i the same as it would have been if the data were normal, namely 1.349σ.) Under this Cauchy assumption, a different interval (a', b') would be computed using the same observed data values $x_1,\ldots, x_n$. The change from the interval (a, b) to the interval (a', b') measures the sensitivity of the process of forming an interval estimate to this change of the assumption about the distribution of the data. This type of sensitivity of the process of forming an inference differs somewhat from the type of sensitivity of a particular procedure that was described earlier. Sensitivity of process is not a uniquely Bayesian concern, however, and it can also be measured for changes to assumptions in non-Bayesian inference.

There have been some successful attempts to take considerations of sensitivity to assumptions into account explicitly in the formulation of Bayesian models. Model uncertainty (see Draper, 1995) and Bayesian model averaging (Hoeting et al., 1999) attempt to develop methodology for expressing directly in the modeling process the belief that more than one out of several competing statistical models might be appropriate for the data, and it may not be clear which one is best. For example, one might not be able to decide whether to model data as normal random variables or as Cauchy random variables. The methods of model uncertainty and model averaging provide ways to pursue both models (as well as others that might seem plausible) without having to pretend as if we really believed firmly in precisely one of them.

Finally, there have been some methods developed to deal with specific common violations of assumptions. The assumption that all observations in a sample have the same distribution has received attention particularly in order to be able to accommodate the occasional outlying observation. One can model data as coming from a mixture of two or more distributions. One of the distributions is the main component on which most interest is focused. The others represent the types of data that might arise when something goes wrong with the data collection procedure. Each observation can be modeled as coming from one of the component distributions with a probability associated with each component. Indeed, using powerful simulation methods (*see* Markov Chain Monte Carlo Methods) one can even compute, for each observation, the conditional probability that it arose from each of the components given the observed data.

Conclusion

This article has discussed the need for carefully acknowledging the probabilistic assumptions made to justify a statistical procedure and some methods for assessing the sensitivity of the procedure to those assumptions. If one believes that there are violations of the assumptions that might reasonably arise in practice, and if the procedure is overly sensitive to violations of those assumptions, one might wish to select an alternative procedure.

There are two popular approaches to choosing alternatives to standard statistical procedures when one fears that assumptions are likely to be violated. One is to use robust procedures, and the other is to use nonparametric procedures. Robust procedures are designed to be less sensitive to violations of specific assumptions without sacrificing too much of the good performance of standard procedures when the standard assumptions hold. Nonparametric procedures are chosen so that their properties can be verified under fewer assumptions. For more details on these types of procedures *see* Robustness.

Essentialism

Nick Haslam and Maria Abou-Abdallah, University of Melbourne, Melbourne, VIC, Australia

Abstract

Psychological essentialism is the belief that an entity or category has an underlying essence that determines its identity. Essentialist intuitions are common in laypeople's thinking about biological kinds and some social categories. In particular, essentialist beliefs about social groups have been shown to have a variety of problematic implications, contributing to social stereotyping, prejudice, and discrimination. This article reviews concepts and empirical studies on essentialism.

What Is Essentialism?

The concept of 'essentialism' originated in philosophy, where it usually refers to the claim that all instances of a certain category – particularly those categories known as 'natural kinds' – share an underlying essence that determines their identity. For instance, the essence of the element *gold* might be its atomic structure and the essence of the species *tiger* might be its DNA structure. In both cases, the proposed essence held in common by all instances of the element or species is causally responsible for their observable features but is not directly observable itself.

Essentialism has been a contentious idea and most philosophers question whether categories do in fact have essences. However, whether or not essentialism is philosophically justified, everyday people appear to hold essentialist intuitions about a variety of categories. This lay intuition, dubbed 'psychological essentialism' (Medin and Ortony, 1989), has been the focus of a variety of research programs within cognitive, developmental, and social psychology (Gelman, 2003). Cognitive psychologists have examined how essentialist thinking enables category learning by leading people to expect deep-seated similarities among the instances they encounter. Developmental psychologists have documented essentialist thinking about biological kinds among preschool children and explored some of the factors that promote it. Social psychologists have explored the implications of essentialist thinking about social groups, and in particular its role in stereotyping and prejudice.

This article will emphasize the social psychological study of essentialist thinking. First we examine theoretical approaches that have animated this work, before turning to a review of several key research findings.

Essentialism in Social Psychology

The first reference to essentialism within social psychology lies in Gordon Allport's classic text, *The Nature of Prejudice* (1954). Allport proposed that a belief in category essences is a fundamental cognitive ingredient of the rigid style of thinking that underpins prejudice. This idea disappeared for almost 40 years before Rothbart and Taylor (1992) argued that people commonly apply essentialist thinking to social categories, such as races and genders. They identified two key aspects of this form of thinking: it led people to see categories as unalterable and 'inductively potent' (i.e., a rich source of information about a person who belongs to the category). Essentializing a social group leads people to see it as fixed and identity-defining. Belonging to such a group, therefore becomes an unchanging and unchangeable part of who they are as a person. According to Rothbart and Taylor, essentialist thinking is destructive because it accentuates perceived differences between social groups and makes existing social arrangements seem inevitable. It also leads people to draw conclusions about people's underlying natures on the basis of their superficial differences and to overlook the role of social, historical, and cultural forces in the shaping of individuals.

Following Rothbart and Taylor's work, several distinct theoretical approaches to the study of essentialist thinking have arisen. One approach, linked to anthropologist Lawrence Hirschfeld (1996), holds that essentialist thinking is one 'mode of construal' that is available to people to make sense of the kinds of people they encounter. Children come into the world cognitively prepared to see essence-based groupings such as 'races.' Another approach, proposed by anthropologist Francisco Gil-White (2001), argues that essentialist thinking is not simply an abstract mode of construal, but a view of categories based on our 'folk biology.' On this account, people construe biological species as if they have distinct essences, and sometimes they may apply this way of thinking to human groupings by analogy. Just as members of a species seek one another out as mates (endogamy) and produce other members as progeny (descent), so do members of ethnic groups. Thus, it is unsurprising that children come to perceive ethnic groups as species-like natural kinds.

Three other major approaches to the study of psychological essentialism have come out of social psychology rather than anthropology. Vincent Yzerbyt and colleagues (e.g., Yzerbyt et al., 1997) have linked essentialist thinking to stereotyping and proposed that it has a system-justifying function. Essentialist beliefs about social categories such as races and genders serve as explanations for existing social stereotypes (e.g., the claim that women are innately maternal or intrinsically unsuited for certain occupations on account of deep-seated genetic or neural factors). Because these essences are understood to be innate and fixed, they make existing social arrangements, such as inequalities, seem inevitable and ordained by nature.

A second psychological account of essentialism is based on the work of Nick Haslam (e.g., Haslam et al., 2000). He has argued that essentialist beliefs about social categories have multiple facets, which form two distinct dimensions. On the one hand, some groups are seen as natural kinds, which involves beliefs that they have crisp, either–or category boundaries (discreteness), a biological basis (naturalness), are invariant across time and cultures (historical stability), and membership of the group is fixed (immutability). On the other hand, some groups are reified or seen as 'entitative.' These groups are believed to be inductively potent (informativeness), homogeneous (uniformity), and to have deep-seated (inherence) and defining features (necessity). Essentialist beliefs are therefore not unitary and social groups can be essentialized in different ways.

An influential third approach to the study of psychological essentialism, albeit one that does not employ the term, examines 'lay theories' about human attributes (Hong et al., 2001). These theories refer to beliefs about the malleability versus fixity of these attributes: for example, people who believe that intelligence can be modified are 'incremental theorists,' whereas those who believe it is fixed are 'entity theorists.' Holding an entity theory is equivalent to having an essentialist belief in the immutability of an attribute, and the many deleterious psychological consequences of entity theories – for motivation, social judgment, and stereotyping – speak to the problematic nature of essentialist thinking.

Empirical Investigations

Numerous psychological studies have now examined the implications, correlates, and determinants of essentialist thinking. Some of these have addressed general questions. For example, it has been shown that those who tend to essentialize differences between people also tend to endorse the accuracy of social stereotypes (Bastian and Haslam, 2006), indicating that essentialism is associated with stereotyping as Yzerbyt and others had proposed. Similarly, it has been shown that essentialist thinking is promoted by the use of generic statements about groups (e.g., "men are aggressive": Leslie and Gelman, 2012). However, most social psychological research on essentialist thinking has studied it in relation to particular social categories. Key findings of this work for the primary social categories of interest will be reviewed below.

Race, Ethnicity, and Culture

Several studies have examined whether individual differences in essentialist beliefs about race or ethnicity are associated with prejudiced attitudes. Generally speaking, this work has found correlations between essentialist thinking and measures of racism, particularly when essentialist beliefs involving genetic factors have been examined (i.e., "genetic essentialism": Dar-Nimrod and Heine, 2011). Relatedly, researchers have found that essentialist thinking among members of a host culture is associated with a less welcoming attitude toward immigrants, and that essentialist thinking among immigrants may also correlate with reluctance to integrate with the host culture. Essentialist thinking also has implications for people's ability to negotiate bicultural identities. One study (Chao et al., 2007) found that Asian-Americans who held racially essentialist beliefs were more troubled when asked about their bicultural identity and were less able to perform a task that required them to switch between their Asian and American identities. Even so, essentialist thinking may have benefits for members of ethnic minorities, such as immigrant communities, by enabling them to maintain a sense of identity, assert a political voice, and resist demands to assimilate (Verkuyten, 2003).

Gender

Gender categories are commonly essentialized even among young children, often in ways that accentuate perceived gender differences. For example, adults are more likely to judge one of their own attributes as unchanging when told it is associated with gender rather than when told it is not, and those who hold biological explanations of gender differences see those differences as more pronounced. There is also evidence that individuals who endorse genetic determinism and biological explanations show higher levels of sexist attitudes (Keller, 2005). This relationship between gender essentialism and gender stereotype endorsement extends to self-stereotyping. For example, women who believe that gender differences are biologically based are more likely to endorse stereotypically feminine traits (Coleman and Hong, 2008), and fathers who held more essentialist views about gender differences provided less direct care for their young children (Gaunt, 2006). In another important study, women performed worse on a math test when told that women tended to perform worse on it than men (i.e., 'stereotype threat'), but only when they had been given a biological essentialist explanation of gender differences in mathematical aptitude (Dar-Nimrod and Heine, 2006).

Sexual Orientation

Essentialist thinking about sexual orientation is interesting in part because it seems to have a somewhat complex association with prejudice. While endorsement of essentialist beliefs about race and gender tend to be associated with racism and sexism, respectively, some essentialist beliefs about homosexuality appear to be related to the absence rather than the presence of antigay attitudes. For example, Haslam and Levy (2006) found that antigay attitudes were associated with the essentialist belief that homosexuality is a discrete category, but were negatively associated with the essentialist beliefs that homosexuality is immutable and historically stable. Importantly, these belief dimensions predicted antigay attitudes independently of established predictors of prejudice such as authoritarianism and political conservatism. More religious people held more negative attitudes because, in part, they believed homosexuality to be mutable, and men held more negative attitudes than women because they believed it to be more discrete.

Mental Disorder

Psychologists have recently begun to study the implications of essentialist beliefs about mental disorders. Such beliefs – that disorders are natural kind with sharp boundaries and biological determinants – roughly corresponds to the biomedical or disease model of mental disorders. Research has shown that many people do in fact hold essentialist beliefs about at least some mental disorders (Ahn et al., 2006) and that these beliefs are linked to prejudice toward those who suffer from them (psychiatric stigma). A growing body of evidence shows that people who endorse more biomedical explanations for mental disorders tend to have less favorable attitudes toward sufferers. Research by Phelan (2005) indicates how 'genetic essentialist' beliefs about mental disorders might promote rather than reduce stigma, and that genetic attributions increase the perceived seriousness and persistence of mental disorders, as well as the perceived risk that the condition would affect the family members of those afflicted.

Personality

Some research beliefs about personality attributes has focused on the extent to which personality traits are seen *as* essences. Although all traits are to some extent essentialized, where the trait concept implies some degree of fixity and underlying causal influence on behavior, some dispositions may be more essentialized than others. Much of this work has examined the development of children's beliefs about the innateness and stability of traits. Giles (2003), for example, shows that children tend to hold essentialist beliefs about aggressiveness, where children who exhibit it are seen as likely to remain that way, and their aggressiveness is attributed to intrinsic rather than environmental factors. Among adults, the traits that are highly essentialized tend to be those that are seen as desirable, prevalent, and emotion-related. As deep-seated essences, these traits are seen as particularly central to a person's identity and to 'human nature' (Haslam et al., 2004).

Conclusions

Psychological essentialism is an intriguing concept that has generated multiple lines of theory and research across several of psychology's subdisciplines. Although at one level, they reflect abstract 'ontological' intuitions about the nature of social reality, at another they have important implications for everyday social perception and intergroup relations. People who tend to essentialize the social world tend to believe in the reality of social stereotypes, form rapid category-based judgments about other people and, with some exceptions, hold more negative attitudes toward traditionally stigmatized and disadvantaged groups. When they hold essentialist beliefs about their own groups, they tend to be constrained by in-group stereotypes and to have more difficulty in navigating the complexities of their identities. Overall, essentialist thinking tends to produce an image of the social world as composed of distinct identities and to deepen the divides between them. For this reason, it is an important topic of study for social and developmental psychologists.

Abstract

In parametric statistical inference, knowledge about a population parameter yields knowledge about the entire population. Thus, methods of estimating population parameters are cornerstones to statistical analysis. Point estimators provide a single value as an estimate of a parameter. Set estimators provide a set of possible values. Set estimators quantify uncertainty about the parameter through the size of the set and the probability of the set covering the parameter. Various methods for deriving point and set estimators and various methods for evaluating estimators are discussed.

Introduction

When sampling from a population described by a density or mass function $f(x|\theta)$, knowledge of θ yields knowledge of the entire population. Hence, it is natural to seek a method of finding a good estimator of the point θ, that is, a good *point estimator*. However, a point estimator alone is not enough for a complete inference, as a measure of uncertainty is also needed. For that, we use a *set estimator* in which the inference is the statement that $\theta \in C$ where $C \subset \Theta$, Θ is the parameter space (set of all possible values of θ), and $C = C(\boldsymbol{x})$ is a set determined by the value of the data, $\boldsymbol{X} = \boldsymbol{x}$, observed. If θ is real-valued, then we usually prefer the set estimate C to be an interval. Our uncertainty is quantified by the size of the interval and its probability of covering the parameter.

Point Estimators

In many cases there will be an obvious or natural candidate for a point estimator of a particular parameter. For example, the sample mean is a natural candidate for a point estimator of the population mean. However, when we leave a simple case like this, intuition may desert us, so it is useful to have some techniques that will give reasonable candidates for consideration. Those that have stood the test of time include these.

Method of Moments

The method of moments (MOM) is, perhaps, the oldest method of finding point estimators, dating back at least to Karl Pearson in the late 1800s. One of the strengths of MOM estimators is that they are usually simple to use and almost always yield some sort of estimate. In many cases, unfortunately, this method yields estimators that may be improved upon.

Let $\boldsymbol{X} = (X_1, \ldots, X_n)$ be a sample from a population with density or mass function $f(\boldsymbol{x}|\theta_1, \ldots, \theta_k)$. MOM estimators are found by equating the first k sample moments to the corresponding k population moments. That is, we define the sample moments by $m_j = \sum_{i=1}^{n} X_i^j/n$ and the population moments by $\mu_j(\theta_1, \ldots, \theta_k) = E_{\boldsymbol{\theta}}\boldsymbol{X}^j$ for $j = 1, \ldots, k$. Then we set $m_j = \mu_j(\theta_1, \ldots, \theta_k)$ and solve for $\theta_1, \ldots, \theta_k$. This solution is the MOM estimator of $\theta_1, \ldots, \theta_k$.

Maximum Likelihood

For a sample $\boldsymbol{X} = (X_1, \ldots, X_n)$ from $f(\boldsymbol{x}|\theta_1, \ldots, \theta_k)$, the likelihood function is defined by

$$L(\boldsymbol{\theta}|\boldsymbol{x}) = \prod_{i=1}^{n} f(x_i|\theta_1, \ldots, \theta_k)$$

The values of $\theta_1, \ldots, \theta_k$ that maximize this function are those parameter values for which the observed sample $\boldsymbol{x}$ is most likely and are called the maximum likelihood estimators (MLEs). If the likelihood function is differentiable (in θ_i), the MLEs can often be found by solving

$$\frac{\partial}{\partial\theta_i}\log L(\boldsymbol{\theta}|\boldsymbol{x}) = 0, \quad i = 1, \ldots, k$$

where the vector with coordinates $\frac{\partial}{\partial\theta_i}\log L(\boldsymbol{\theta}|\boldsymbol{x})$ is called the *score function* (see Schervish, 1995: Section 2.3).

Example: If $\boldsymbol{X} = (X_1, \ldots, X_n)$ is a sample from a Bernoulli (p) population, the likelihood function is

$$L(p|\boldsymbol{x}) = \prod_{i=1}^{n} p^{x_i}(1-p)^{1-x_i}$$

and differentiating $\log L(p|\boldsymbol{x})$ and setting the result equal to zero gives the MLE $\widehat{p} = \sum_{i=1}^{n} x_i/n = \bar{x}$, the sample mean. This is also the MOM estimator.

If instead we have a sample $\boldsymbol{X} = (X_1, \ldots, X_n)$ from a binomial (k, p) population, where p is known and k is unknown, the likelihood function is

$$L(k|\boldsymbol{x}, p) = \prod_{i=1}^{n} \binom{k}{x_i} p^{x_i}(1-p)^{k-x_i}$$

and the MLE must be found by the numerical maximization. The MOM gives the closed form solution

$$\widehat{k} = \frac{\bar{x}^2}{\bar{x} - \sum_i (x_i - \bar{x})^2/n},$$

which can take on negative values. This illustrates a shortcoming of the MOM, one not shared by the MLE. Another, perhaps more serious shortcoming of the MOM estimator is that it may not be based on a sufficient statistic (*see* Statistical Sufficiency), which means it could be inefficient in not using all of the available information in a sample. In contrast, both MLEs and Bayes estimators (*see* Bayesian Statistics) are based on sufficient statistics.

[†] Deceased.

Bayes

In the Bayesian paradigm a random sample $X_1, \ldots, X_n$ is drawn from a population indexed by θ, where uncertainty about θ can be described by a probability distribution (called the *prior distribution*). After the sample is taken, the prior distribution is updated with this sample information. The updated prior is called the *posterior distribution*.

If we denote the prior distribution by $\pi(\theta)$ and the sampling distribution by $f(\boldsymbol{x}|\theta)$, then the posterior distribution, the conditional distribution of θ given the sample, $\boldsymbol{x}$, is

$$\pi(\theta|x) = \frac{f(x|\theta)\pi(\theta)}{m(x)},$$

where $m(x) = \int f(x|\theta)\pi(\theta)\mathrm{d}\theta$ is the marginal distribution of $\boldsymbol{x}$.

Example: Let $\boldsymbol{X} = (X_1, \ldots, X_n)$ be a sample from a Bernoulli (p) population. Then $Y = \sum_i X_i$ is binomial (n, p). If p has a beta (α, β) prior distribution, that is

$$\pi(p) = \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} p^{\alpha-1}(1-p)^{\beta-1},$$

the posterior distribution of p given y is

$$\begin{aligned}\pi(p|y) &= \frac{f(y|p)\pi(p)}{m(y)} \\ &= \frac{\Gamma(n+\alpha+\beta)}{\Gamma(y+\alpha)\Gamma(n-y+\beta)} p^{y+\alpha-1}(1-p)^{n-y+\beta-1},\end{aligned}$$

which is a beta distribution with parameters $y+\alpha$ and $n-y+\beta$. The posterior mean, a common Bayes estimator of p, is

$$\widehat{p}_B = \frac{y+\alpha}{\alpha+\beta+n}.$$

Evaluating Point Estimators

There are many methods of deriving point estimators (robust methods, least squares, estimating equations, invariance), but the three in Section Point Estimators are among the most popular. No matter what method is used to derive a point estimator, it is important to evaluate the estimator using some performance criterion.

One way of evaluating the performance of a point estimator W of a real-valued parameter θ is through its *mean squared error* (MSE), defined by

$$\mathrm{MSE}_\theta W = E_\theta(W-\theta)^2 = \mathrm{Var}_\theta W + (E_\theta W - \theta)^2.$$

Defining the bias of a point estimator by $\mathrm{Bias}_\theta W = \mathrm{E}_\theta W - \theta$ yields $\mathrm{MSE}_\theta W = \mathrm{Var}_\theta W + (\mathrm{Bias}_\theta W)^2$. An estimator whose bias is identically (in θ) equal to zero is called *unbiased*.

For an unbiased estimator we have $\mathrm{MSE}_\theta W = \mathrm{Var}_\theta W$; if an estimator is unbiased, its MSE is equal to its variance. If $\boldsymbol{X} = (X_1, \ldots, X_n)$ is a sample from a population with mean θ and variance σ^2, the sample mean is an unbiased estimator of θ $(E_\theta \overline{X} = \theta)$, and

$$\mathrm{MSE}_\theta \overline{X} = \mathrm{Var}_\theta \overline{X} = \frac{\sigma^2}{n}.$$

Controlling bias does not guarantee that MSE is minimized. In particular, it is sometimes the case that a trade-off occurs between variance and bias. For example, in sampling from a normal population with variance σ^2, the usual unbiased estimator of σ^2, $S^2 = \sum_{i=1}^n (X_i - \overline{X})^2/(n-1)$, has $\mathrm{MSE}_\sigma S^2 = 2\sigma^4/(n-1)$. An alternative estimator of σ^2 is the MLE $\widehat{\sigma}^2 = \sum_{i=1}^n (X_i - \overline{X})^2/n = (n-1)S^2/n$. This is a biased estimator of σ^2 with

$$\mathrm{MSE}_\sigma \widehat{\sigma}^2 = \frac{2n-1}{n^2}\sigma^4 < \frac{2}{n-1}\sigma^4 = \mathrm{MSE}_\sigma S^2,$$

showing that $\widehat{\sigma}^2$ has smaller MSE than S^2. Thus, by trading off variance for bias, the MSE is improved.

Measuring performance by the squared difference between the estimator and a parameter is a special case of a function called a *loss function*. The study of the performance and optimality of estimators evaluated through loss functions is a branch of decision theory. In addition to MSE, based on squared error loss, another popular loss function is absolute error loss, $L(\theta, W) = |W - \theta|$. Both of these loss functions increase as the distance between θ and W increases, with minimum value $L(\theta, \theta) = 0$. That is, the loss is minimum if the estimator is correct.

In a decision theoretic analysis an estimator is evaluated through its *risk function*. For an estimator W of θ, the risk function is $R(\theta, W) = \mathrm{E}_\theta L(\theta, W)$; the risk function is the average loss. If the loss is squared error, the risk function is the MSE.

Using squared error loss, the risk function (MSE) of the binomial Bayes estimator of p is

$$\begin{aligned}\mathrm{MSE}_p \widehat{p}_B &= \mathrm{Var}_p \widehat{p}_B + \left(\mathrm{Bias}_p \widehat{p}_B\right)^2 \\ &= \frac{np(1-p)}{(\alpha+\beta+n)^2} + \left(\frac{np+\alpha}{\alpha+\beta+n} - p\right)^2.\end{aligned}$$

In the absence of good prior information about p we might choose α and β to make the risk function of $\widehat{p}_B$ constant (called an *equalizer rule*). The solution is $\alpha = \beta = \sqrt{n/4}$, yielding

$$\mathrm{MSE}_p \widehat{p}_B = \frac{n}{4(n+\sqrt{n})^2}.$$

We can also use a Bayesian approach to the problem of loss function optimality, where we would use the prior distribution to compute an average risk, $\int_\Theta R(\theta, W)\pi(\theta)\mathrm{d}\theta$, known as the *Bayes risk*. We then find the estimator that yields the smallest value of the Bayes risk. Such an estimator is called the Bayes rule with respect to a prior π.

To find the Bayes decision rule for a given prior π we write the Bayes risk as

$$\int_\Theta R(\theta, W)\pi(\theta)\mathrm{d}\theta = \int_x \left[\int_\Theta L(\theta, W(x))\pi(\theta|x)\mathrm{d}\theta\right] m(x)\mathrm{d}x,$$

where the quantity in square brackets is the expected value of the loss function with respect to the posterior distribution, called the *posterior expected loss*. It is a function only of $\boldsymbol{x}$ and not a function of θ. Thus, for each $\boldsymbol{x}$, if we choose the estimate $W(\boldsymbol{x})$ to minimize the posterior expected loss, we will minimize the Bayes risk, and $W(\boldsymbol{x})$ is the Bayes rule.

For squared error loss, the posterior expected loss is minimized by the mean of the posterior distribution. For absolute error loss, the posterior expected loss is minimized by the median of the posterior distribution. If $\boldsymbol{X} = (X_1, \ldots, X_n)$

is a sample from a normal population, with mean θ and variance σ^2 ($n(\theta, \sigma^2)$), and the prior on θ is $n(\mu, \tau^2)$, the posterior mean is

$$E(\theta|x) = \frac{\tau^2}{\tau^2 + (\sigma^2/n)}\bar{x} + \frac{\sigma^2/n}{\tau^2 + (\sigma^2/n)}\mu.$$

Because the posterior distribution is normal, it is symmetric and the posterior mean is the Bayes estimator for both squared error and absolute error loss. The posterior mean in our binomial/beta example, $\widehat{p}_B = (y + \alpha)/(\alpha + \beta + n)$, is the Bayes estimator for squared error loss.

We can loosely group evaluation criteria into large sample (asymptotic) methods and small sample methods. Our calculations using MSE and risk functions illustrate small sample methods. In large samples, MLEs typically perform very well, being asymptotically normal and efficient, that is, attaining the smallest possible variance. Other types of estimators that are derived in a similar manner (for example, M-estimators – *see* Robustness in Statistics) also share good asymptotic properties. For a detailed discussion see Casella and Berger (2001), Lehmann (1999), Stuart et al. (1999), or Lehmann and Casella (1998: Chapter 6).

Interval Estimation

Reporting a point estimator of a parameter θ only provides part of the story. The story becomes more complete if an assessment of the error of estimation is also reported. Informally, this can be accomplished by giving an estimated standard error of the estimator, and, more formally, this becomes the reporting of an interval estimate. If $\boldsymbol{X} = \boldsymbol{x}$ is observed, an *interval estimate* of a parameter θ is a pair of functions, $L(\boldsymbol{x})$ and $U(\boldsymbol{x})$, for which the inference $\theta \in (L(x), U(x))$ is made. The *coverage probability* of the random interval $(L(\boldsymbol{X}), U(\boldsymbol{X}))$ is the probability that $(L(\boldsymbol{X}), U(\boldsymbol{X}))$ covers the true parameter, θ, and is denoted by $P_\theta(L(\boldsymbol{X}) < \theta < U(\boldsymbol{X}))$.

By definition the coverage probability depends on the unknown θ, so it cannot be reported. What is typically reported is the *confidence coefficient*, the infimum of the coverage probabilities, $\inf_\theta P_\theta(L(X) < \theta < U(X))$.

If $\boldsymbol{X} = (X_1, \ldots, X_n)$ is a sample from a population with mean θ and variance σ^2, a common interval estimator for θ is

$$\bar{x} - 2\frac{s}{\sqrt{n}} < \theta < \bar{x} + 2\frac{s}{\sqrt{n}},$$

where $\bar{x}$ is the sample mean and s is the sample standard deviation. The validity of this interval can be justified from the Central Limit Theorem, because

$$\frac{\overline{X} - \theta}{S/\sqrt{n}} \to n(0, 1),$$

the standard normal distribution. We then see that the coverage probability (and confidence coefficient) of this interval is approximately 95%.

The above interval is a large sample interval, because its justification is based on an asymptotic property. There are many methods for constructing interval estimators that are valid in small samples, including these.

Inverting a Test Statistic

There is a correspondence between acceptance regions of hypothesis tests (*see* Hypothesis Testing in Statistics) and confidence sets, summarized in the following theorem.

Theorem 1: For each $\theta_0 \in \Theta$, let $A(\theta_0)$ be the acceptance region of a level α test of H_0: $\theta = \theta_0$. For each sample point $\boldsymbol{x}$, define a set $C(\boldsymbol{x})$ in the parameter space by

$$C(x) = \{\theta_0 : x \in A(\theta_0)\}.$$

Then the random set $C(\boldsymbol{X})$ is a confidence set with confidence coefficient $1 - \alpha$. Conversely, let $C(\boldsymbol{X})$ be a $1 - \alpha$ confidence set. For each $\theta_0 \in \Theta$, define

$$A(\theta_0) = \{x : \theta_0 \in C(x)\}.$$

Then $A(\theta_0)$ is the acceptance region of a level α test of H_0: $\theta = \theta_0$.

Example: If $\boldsymbol{X} = (X_1, \ldots, X_n)$ is a sample from an $n(\theta, \sigma^2)$ population, with σ^2 known, the level α test of H_0: $\theta = \theta_0$ versus H_1: $\theta \neq \theta_0$ will accept the null hypothesis, if $|\bar{x} - \theta_0|/(\sigma/\sqrt{n}) < z_{\alpha/2}$. This inequality can be equivalently written as

$$\bar{x} - z_{\alpha/2}\frac{\sigma}{\sqrt{n}} < \theta_0 < \bar{x} + z_{\alpha/2}\frac{\sigma}{\sqrt{n}}.$$

This interval of θ values, for which the null hypothesis is accepted at level α, is a $1 - \alpha$ confidence interval for θ.

Pivotal Intervals

An elegant method of constructing set estimators is the use of pivotal quantities (Barnard, 1949). A random variable, $Q(\boldsymbol{X}, \theta) = Q(X_1, \ldots, X_n, \theta)$, is a pivotal quantity (or pivot), if the distribution of $Q(\boldsymbol{X}, \theta)$ is independent of all parameters. If we find a set C such that $P(Q(\boldsymbol{X}, \theta) \in C) = 1 - \alpha$, then the set $C(\boldsymbol{X}) = \{\theta: Q(\boldsymbol{X}, \theta) \in C\}$ has coverage probability $1 - \alpha$.

In *location* and *scale* cases, once we calculate the sample mean $\overline{X}$ and the sample standard deviation S, examples of pivots are:

Form of pdf	*Type of pdf*	*Pivot*
$f(x - \theta)$	Location	$\overline{X} - \theta$
$f(x/\sigma)/\sigma$	Scale	S/σ
$\dfrac{f((x - \theta)/\sigma)}{\sigma}$	Location–scale	$\dfrac{\overline{X} - \theta}{S}$

In general, differences are pivotal for location problems, while ratios (or products) are pivotal for scale problems. *see* Fiducial and Structural Statistical Inference.

Example: Let $\boldsymbol{X} = (X_1, \ldots, X_n)$ be a sample from an exponential (λ) population, and let $T = \sum_{i=1}^n X_i$. T has a gamma (n, λ) distribution. This gamma pdf is

$$f(t|\lambda) = \Gamma(n)\left(\frac{t}{\lambda}\right)^{n-1} e^{-t/\lambda}\frac{1}{\lambda}.$$

In this gamma pdf t and λ appear together as t/λ, and, in fact, the gamma (n, λ) pdf is a scale family in λ. If $Q(T, \lambda) = 2T/\lambda$, then $Q(T, \lambda)$ has a gamma $(n, 2)$ (also called χ^2_{2n}) distribution,

which does not depend on λ. Hence, the quantity $Q(T, \lambda)$ is a pivot, and a $1-\alpha$ pivotal interval is

$$\frac{2T}{\chi^2_{2n,\alpha/2}} < \lambda < \frac{2T}{\chi^2_{2n,1-\alpha/2}},$$

where $P(\chi^2_{2n} > \chi^2_{2n,\alpha}) = \alpha$.

Bayesian Intervals

If $\pi(\theta|\boldsymbol{x})$ is the posterior distribution of θ given $\boldsymbol{X} = \boldsymbol{x}$, then for any set $A \subset \Theta$ the posterior probability of A is

$$P(\theta \in A|x) = \int_A \pi(\theta|x)\mathrm{d}\theta.$$

If $A = A(\boldsymbol{x})$ is chosen so that this posterior probability is $1-\alpha$, then A is called a $1-\alpha$ *credible set* for θ.

The interpretation of the Bayes interval estimator is different from the classical intervals. In the classical approach to assert 95% coverage is to assert that in 95% of repeated experiments the realized intervals will cover the true parameter. In the Bayesian approach a 95% coverage means that the probability is 95% that the parameter is in the realized interval. In the classical approach the randomness comes from the repetition of experiments, while in the Bayesian approach the randomness comes from uncertainty about the value of the parameter (summarized in the prior and posterior distributions).

Example: Let $\boldsymbol{X} = (X_1, \ldots, X_n)$ be a sample from an Poisson (λ) population, and assume that λ has a gamma (a, b) prior, where a is an integer. The posterior distribution of λ is

$$\pi(\lambda|x) \text{ is gamma}\left(a + \sum_{i=1}^{n} x_i, \frac{b}{nb+1}\right).$$

Thus the posterior distribution of $[2(nb+1)/b]\lambda$ is $\chi^2_{2(a+\sum_i x_i)}$, and a $1-\alpha$ Bayes credible interval for λ is

$$\frac{\chi^2_{2(a+\sum_i x_i),1-\alpha/2}}{2(nb+1)/b} < \lambda < \frac{\chi^2_{2(a+\sum_i x_i),\alpha/2}}{2(nb+1)/b}.$$

We can form a Bayes credible set by using the *highest posterior density* (HPD) region of the parameter space, also. That is, choose c so that the set $C(x) = \{\lambda: \pi(\lambda|x) > c\}$ satisfies

$$1-\alpha = P(\lambda \in C(x)|x).$$

Such a construction is optimal in the sense of giving the shortest interval for a given $1-\alpha$, although if the posterior is multimodal the set may not be an interval.

Other Intervals

We have presented two-sided parametric confidence intervals that are constructed to cover a parameter. Other types of intervals include one-sided intervals, distribution-free intervals, prediction intervals, and tolerance intervals.

One-sided intervals are those in which only one endpoint is estimated, such as $\theta \in (L(X), \infty)$. Distribution-free intervals are intervals whose probability guarantee holds with few (or no) assumptions on the underlying population. The other two interval definitions, together with the usual confidence interval, provide us with a hierarchy of inferences, each more stringent than the previous.

Let $\boldsymbol{X} = (X_1, \ldots, X_n)$ be a sample from a population with cdf $F(\boldsymbol{x}|\theta)$. If $C(\boldsymbol{x}) = (L(\boldsymbol{x}), U(\boldsymbol{x}))$ is an interval, for a specified value $1-\alpha$ it is a:

1. *confidence* interval if, for all θ, $P_\theta(L(X) < \theta < U(X)) \geq 1-\alpha$;
2. *prediction* interval if, for all θ, $P_\theta(L(X) < X_{n+1} < U(X)) \geq 1-\alpha$, where X_{n+1} is an independent, new observation;
3. *tolerance* interval if, for all θ and for a specified value p, $P_\theta(F(U(X)|\theta) - F(L(X)|\theta) \geq p) \geq 1-\alpha$.

So a confidence interval covers a parameter, a prediction interval covers a new observation, and a tolerance interval covers a proportion of the population. Each gives a different inference with the appropriate one being dictated by the problem at hand. Vardeman (1992) discusses the importance of each of these intervals.

Conclusions

Point estimation is one of the cornerstones of statistical analysis and the basic element on which many inferences are based. Inferences using point estimators gain statistical validity when they are accompanied by an interval estimate, providing an assessment of the uncertainty. We have mainly discussed parametric point and interval estimation, where we assume that the underlying model is correct. Such an assumption can be questioned, and considerations of nonparametric or robust alternatives can address this (*see* Robustness). For more on these subjects see, for example, Boos and Stefanski (2013), Hettmansperger and McKean (1998), or Staudte and Sheather (1990). Full treatments of parametric point and interval estimation can be found in Casella and Berger (2001), Stuart et al. (1999), or Schervish (1995).

Ethical Codes, Professional: Business Codes

Josef Wieland, Zeppelin University, Friedrichshafen, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Business codes are a functional equivalent to national or internal deficits of regulation by way of directing companies to self-binding and self-control. They are the foundation of collective and individual perception and provide shared mental models for cooperation, and they determine and define the identity of those corporations that bind themselves to standards of behavior. They show a corporation's responsibility and can assure economic benefit as well as reduce the risk of losing economic and social reputation. These effects can be reached only by actually maintaining the standards of behavior within the business routine of the company. For that purpose, they have to be implemented and integrated into the operative processes of the organization and its management. One of the most important instruments in this respect is values management systems.

Business codes are formal or informal standards of behavior that give structure and direction to economic action and behavior. They codify the values of a corporation, an industry, or a whole sector, and thereby create identity and shape one's perception. Conceived of as self-binding acts, business codes enable and provide constraints to collective actions within the economy. In Western economies, as well as in the emergence of a global economy, they play an important role as governance structures because of, and insofar as they make possible, the expansion of economical and societal cooperation.

History and Actuality

Voluntary standards of behavior in the economy as a means of self-binding and constraint can be found in early history. Their emergence is connected to the guilds of craftsmen and merchants in the Middle Ages, where they regulated behavior toward the other members of the guilds, customers, coworkers, and employees. In the beginning, they were informal and derived from tradition, common rites, and the customs belonging to a trade. With the expansion of long-distance trading, these standards were laid down and were adopted by traveling merchants. Thus, they became increasingly formal, which meant that they became enforceable by third parties. These early business codes served to ensure contracts concerning future delivery and payment of goods and were enforceable by guild courts and the threat of ostracism (Mitchell, 1969).

To the extent that national and international business laws were established and enforceable by government bodies during the nineteenth century, private standards of behavior based on the threat of ostracism and loss of reputation gradually started to lose their importance. But in the 1970s, a renaissance of private standards of behavior emerged from two main sources. The first was the internationalization and globalization of markets and production networks, which were and still are unaccompanied by developments of political, juridical, and cultural institutions and their enforceability. Such business codes include maintaining human rights as well as social and legal standards in cooperative relationships, for example, with customers, suppliers, and partners, and they define common perspectives in areas where different values standards as well as cross-cultural values conflicts hinder the establishment of transcultural teams (cf Wieland, 2010a).

Business codes are an element of an emerging normative order of globally accepted norms of good behavior (Dunning, 2003). In developing global standards, new players like the BRICS states (i.e., Brazil, Russia, India, China, and South Africa) are very likely to play an increasingly decisive role. Therefore, business codes must reflect cultural diversity and at the same time transcultural values. Real globalization of the economy and society, however, still is accompanied by the twofold problem of institutional and organizational deficit. In contrast to international standards, which are decided on by individual states or intergovernmental organizations and subsequently enforced throughout the world, the design and establishment of global and globally accepted standards and rules is still in a development process. This is due, not least, to a lack of internationally recognized and motivated organizations capable of promoting such a development process for globally accepted norms to regulate fair individual and organizational behavior. The Human Guidelines on Business and Human Rights, the Organization for Economic Cooperation and Development (OECD) Guidelines for Multinational Enterprises, the United Nations Global Compact, or the International Labor Organization 'core norms' are exemplary and valuable examples of the emergence of a global normative order. In this context, multistakeholder dialogues as standard setters are of utmost importance (Wieland, 2011).

The second source was the organizational decentralization of corporations, which led to an increase in 'gray areas' and decreasing possibilities of utilizing direct monitoring and control mechanisms. Here, business codes have to define a common set of values to give the company identity and a behavioral orientation. To reach this aim, it needs to form vision, mission, and value statements, compliance standards, and rules for dealing with the company's stakeholders (customers, employees, suppliers, environment) (Weaver, 1993). Such standards of behavior can be enforced by sanctions and incentives within the company. With regard to

customers and suppliers, the companies' reputation and brand names are important enforcing mechanisms.

Minimum Standards, Problem Standards, and Corporate Standards

Business codes are characterized by self-binding possibilities of private enforcement and by the identity of the actors. Self-binding by voluntary constraints of action, certainty of expectation in contracts by enforcement possibilities (sanctions, incentives, reputation), and the creation of corporate identity by means of codified and realized values in business routine make standards of behavior a functional equivalent to national regulations and laws. Whenever national or supernational regulations and their enforcement do not exist or are not feasible, regardless of the identity of an actor, private standards of behavior become a dominating issue of economic and societal governance. Therefore, they are known as 'soft laws' (Fatouros, 1994). By creating certainty of expectation for economic action in societies that are characterized by division of labor, business codes directly influence the state of welfare in any given society. With these reliable and trustworthy rules, more cooperation and more transactions are made possible than without them.

The distinction between minimum standards, problem standards, and corporate standards enables us to group modern business codes along with the kinds of cooperation and transactions that are steered by them.

Minimum Standards

Minimum standards are instruments serving the governance of global business transactions – for example, Guidelines for Multinational Enterprises (OECD, update 2011) and Corporate Governance Guidelines (OECD, 1991/1998/2004), a Code of Conduct on Transnational Corporations (United Nations, 1994), and ISO 26.000 Social Responsibility (SR) (ISO 2010), to name just a few. They define minimum requirements for such areas as working conditions, involvement of unions, safety at work, consumer protection, competition, technology transfer, investment in developing countries, corruption, and human rights.

Minimum standards emerge from bargaining processes between national governments, national and international organizations of employers and unions, and any nongovernmental organizations (NGOs) involved, which are directed by a recognized international organization (Fatouros, 1994). Their status is precarious. They are voluntary but not arbitrary. These agreements are obligatory for the signing parties, although they cannot be enforced by law. Whether it is possible to implement them therefore depends on the voluntary efforts of the contractors as well as on whether it is possible to take action against rule breakers or to damage their reputation in a cost-generating way. Their strength lies in the fact that they provide standards that possess some chance of realization, although there is no suitable international law available or accessible. Their weak points are the difficulty of implementing and controlling them. Nevertheless, they are a significant component of economic globalization because they are a functional equivalent to the still underdeveloped international business law. Hence, they create a certain formal and political certainty within the world economy that is a crucial demand for worldwide prosperity.

Problem Standards

Problem standards define proposals of behavior that help to solve certain problems and that go far beyond the rules of the game asserted through the minimum standards. One example from the area of ecological sustainability is the 'responsible care' process of the chemical industry's international associations and companies. From the area of social responsibility, the efforts to abolish child labor and forced labor according to the Council on Economic Priorities' standard Social Accountability 8000 may be cited. In the field of sustainability, Rainforest Alliance Certified is a pertinent example. Problem standards are highly ambitious compared with the potentialities and mentality of many companies. Hence, they are accepted by only a few companies, mostly by those that have elaborated them, usually in cooperation with NGOs. This may happen in associations or chambers of commerce or in loose assemblies of those companies for whose business actions the problem in question is instantly relevant. Their strength lies in their model character and in the fact that they make practical experiences concerning these standards possible. Their weakness lies in what is mostly very difficult control and in the possible competitive disadvantages for those companies that do not succeed in overcoming the costs of implementing and keeping the standards through prices.

Corporate Standards

Corporate standards codify the constitutive and action-directing values of a corporation. As codes of conduct or codes of ethics, they are components of corporate governance, that is, of the leading, steering, and controlling mechanisms of an economic organization. They also are expressions of the distinct philosophy and policy of the corporation. The values of a corporation can be classified as performance values (e.g., profit, quality), cooperative values (e.g., loyalty, team spirit), communication values (e.g., respect, transparency), and moral values (e.g., integrity, fairness) (Wieland, 2000). A firm gains identity and distinctiveness as soon as a specific values mix drawn from these four classes of values endows it with a particular profile. Particularity here means that it fits best with the promises of the company, its tradition and history, and the aspired direction of future developments. As a rule, these business codes provide regulations for coping with suppliers and customers, shareholders, and employees, as well as rules of law and of environment protection. They are part of an overall values management system by which the business codes are operated and pursued in corporate practice. Normally, this is executed by means of internal and external communication, by training, by ethics officers, and by being incorporated in labor contracts and other policies and procedures, and the system is controlled by monitoring audits (Weaver et al., 1999; Wieland, 2010b).

Values management systems thus are a fundamental presupposition to solve all the potential conflicts of interest in everyday business (Davis and Stark, 2001).

The systems themselves can be divided into law-driven and values-driven ones (Paine, 1994). Although the first are compliance programs that focus on the observation of the rules of law and are organized by the legal or compliance department of a corporation, the latter as values management systems aim at a comprehensive development of the corporate culture specifically concerning relations with the totality of stakeholders. Codes of ethics therefore never make any statements about existing matters of fact, and they never stand in for the moral consensus of all parties that are interested in the company. It is just the other way around. They define the values of an organization against all stakeholders and declare them conditional for further interaction. They express the normative side of the firm. As conditions of cooperation with and within an organization, these values are shaped like commitments of performance. The company commits itself to these values and promises to continually work on the fulfillment of its commitment. This makes it obligatory for all stakeholders also to bind themselves to the values. In the last decade of the twentieth century, about 80% of the big US companies had adopted such codes (Center for Business Ethics, 1992; Stevens, 2008; Kaptein, 2008). In the second decade of the twenty-first century, a code of ethics or code of conduct for big and multinational companies has become a standard in Europe.

Apart from the reasons for the renaissance of business ethics mentioned earlier, another important factor is legal developments. Because of the introduction in the United States and the United Kingdom of organizational liability in cases of deviant behavior of employees, incentive systems have been installed that demonstrate the due diligence and make it financially worthwhile to document before the court the implementation and communication of a code of ethics, so that in case of an individual breach of law, the organization cannot be held responsible for it (U.S. Sentencing Commission, 1995). Legal developments similar to this can be observed in Europe (U.K. Bribery Act, 2011). In this context, business codes aim to achieve a higher level of transparency and thereby enhance the means of control in the corporation. The strength of standards of behavior in corporations is that they are highly specific and integrate the involved actors in maintaining them by the implementation of incentives. They cause problems, however, for any form of control and by the fact that they have to be introduced into the operative actions (policies and procedures) of the corporation in a relevant way.

Functions and Effect

Although all the three kinds of business codes refer to different types of cooperation and transactions, they are identical in regard to their functions and effectiveness. These can be differentiated as follows:

1. Business codes are a functional equivalent to national or internal deficits of regulation by way of directing companies to self-binding and self-control.
2. Business codes determine and define the identity of those corporations that bind themselves to standards of behavior. These corporations are distinguished from other organizations in the public arena of realization and communication.
3. Business codes are the basis, as well as a criterion of selection, for corporate decisions. Hence, they define the range of liability a company claims beyond existing law.
4. Business codes are the foundation of collective and individual perception and provide shared mental models for cooperation.
5. Business codes internally and externally indicate the behavioral preferences of an organization and at the same time communicate a challenge to all its stakeholders to bind themselves to them.
6. Business codes provide certainty of expectation in business relations and make possible the building up of mutual trust by creating a check against informational uncertainty and opportunistic behavior.
7. Their prevalence, on the one hand, relies on economic benefits that arise from the acceptance of standards of behavior. On the other hand, one runs the risk of losing economic and social reputation in any case of violation of the legal and moral obligations to which they are committed.
8. The aspects mentioned – self-binding, identity, responsibility, shared mental models, certainty of expectation, building up trust, and reputation – constitute a system of mutual effects that lead to an expansion of economic and societal cooperation and to accompanying gains from trade.
9. These effects can be reached only by actually maintaining the standards of behavior within the business routine of the company. For that purpose, they have to be implemented and integrated into the operative processes of the organization and its management. One of the most important instruments in this respect is values management systems.

Ethical Consumers

Veronika A Andorfer, Göttingen, Germany

Abstract

Ethical consumers are not only concerned with the price and quality of products and services, they also consider the consequences of their consumption practices. Researchers and practitioners alternatively describe these consumers as 'green,' 'sustainable,' 'responsible,' 'socially conscious,' 'conscientious,' 'critical,' 'active,' 'political,' or 'moral.' At the beginning of the 1980s, scholars and professionals used the concept almost exclusively to describe green consumers being mindful of the environmental impact of their day-to-day consumption patterns. Over time, however, it has come to denote a much broader and growing field of contemporary consumer concerns.

Ethical consumers are not only concerned with the price and quality of products and services, they also consider the consequences of their consumption practices. Researchers and practitioners alternatively describe these consumers as 'green,' 'sustainable,' 'responsible,' 'socially conscious,' 'conscientious,' 'critical,' 'active,' 'political,' or 'moral.' At the beginning of the 1980s, scholars and professionals used the concept almost exclusively to describe green consumers being mindful of the environmental impact of their day-to-day consumption patterns. Over time, however, it has come to denote a much broader and growing field of contemporary consumer concerns. Typically, the ethical dimension involves environmental, political, social, or religious aspects when consumers purchase, use, modify, and discard goods and services (Harrison et al., 2007). Cases of ethical consumers are usually attributed to the industrialized markets of North America and Europe.

Standard examples of ethical consumption include buying organic, regional/local, or fair trade produce; boycotting commodities manufactured under dubious working conditions and supporting sweat-free companies; avoiding products tested on animals; investing in firms that operate in a socially responsible manner; recycling waste; compensating CO_2 emissions from ground and air travel; preferring a vegetarian or vegan diet; voluntarily abstaining from purchasing consumer goods; and observing buy nothing days.

As diverse as the manifestations of ethical consumers and their consumption practices in everyday life are the scholarly contributions on the topic. Researchers from wide-ranging disciplines such as agricultural sciences, anthropology, business and marketing, consumer studies, economics, environmental science, philosophy, geography, political science, (social) psychology, sociology, and sustainability studies have explored the individual characteristics and motivations of ethical consumers and the structural determinants of their consumption practices.

Characteristics of Ethical Consumers

Who Are They?

Profiling the ethical consumer is difficult. Researchers find only few sociodemographic variables that consistently link the social bases of ethical consumers (Devinney et al., 2010; Papaoikonomou et al., 2011; Peattie, 2010). Empirical evidence suggests that ethical consumers tend to be older, female, well educated, and have higher-than-average incomes (e.g., Cotte and Trudel, 2009; Papaoikonomou et al., 2011 Tallontire et al., 2001). Researchers have not been successful in identifying ethical consumers on the basis of their personality and personal motivations. Ethical consumers' practices do, however, seem to be guided by religious beliefs and values of universalism, solidarity, and altruism (e.g., Doran, 2009; Doran and Natale, 2011; Peattie, 2010).

What Do They Do?

The diverse profile of ethical consumers is matched by the diversity of practices they pursue in everyday life to demonstrate their principles. To classify ethical consumers' practices, scholars commonly differentiate 'buycotts' (Friedman, 1996) from 'boycotts.' Boycotting – also called negative buying – denotes consumers' refusal to buy products and services that harm the environment, communities, animals, or workers. It may also involve consumers refusing to buy products from a specific company to punish it for its unethical conduct (e.g., North American and European consumers boycotting Nestlé products from 1977 to the present because of the company's aggressive marketing strategy to promote breast milk substitutes in developing countries). Buycotting – or positive buying – involves consumers deliberately choosing ethical products and services over conventional alternatives. In doing so, consumers reward a company for its ethical policies.

In addition to the dichotomy of boycotts and buycotts, scholars identify a variety of other types of ethical consumption practices. 'Consumer action' commonly includes aspects such as lobbying policy makers, writing petitions, and initiating campaigns (e.g., Tallontire et al., 2001: p. 7). Harrison et al. (2007: p. 3) identify three additional types: (1) 'ethical screening/rating of producers' such as publishing ethical consumer magazines to inform consumers about ethical/unethical cooperate behavior; (2) 'relationship purchasing,' for instance, community-supported agriculture; and (3) 'anti-consumerism or sustainable consumerism' understood as consumers trying to avoid unsustainable products entirely. In academic discussions, this latter type is sometimes specified as

'voluntary simplicity/ethical simplifiers' meaning consumers voluntarily cutting down on their total consumption and choosing to live a simpler life to promote their ethical objectives. By contrast, 'sustainable consumer habits' summarizes selected eco-friendly consumer practices such as recycling waste or using water-saving house appliances (Papaoikonomou et al., 2011: p. 213).

A different classification scheme categorizes ethical consumption practices according to ethical consumers' primary areas of concern. These fall broadly into the categories, 'people,' 'politics,' and 'environment' (Yates, 2010: p. 196). Examples include issues such as consumerist lifestyles; free trade in tropical commodities; abusive labor practices; local economy; repressive regimes; environmental sustainability; biodiversity, nature, and endangered species; genetically modified organisms; and animal welfare (Starr, 2009).

Ethical consumers' day-to-day actions are manifold and the list of potential paths of ethical consumption grows continuously. As such, the terms 'ethical consumption' and 'ethical consumers' seem to be incoherent umbrella terms for a wide variety of phenomena in contemporary consumer society rather than a clearly defined set of consumers (Lewis and Potter, 2011). Except for the classical boycott–buycott dichotomy, scholars and practitioners have not yet established a commonly accepted typology of ethical consumption behaviors.

Where Are They?

Scholars and practitioners picture ethical consumers almost exclusively in the industrialized societies of North America, Western Europe, and Scandinavia. However, their geographical scope widens as new middle class consumers arise in the emerging economies of Eastern Europe, Asia, and the global South.

Cases of ethical consumers have mostly been studied in the United States, Canada, the UK, Western and Northern Europe, and to a lesser extent in Australia and the New Zealand (Andorfer and Liebe, 2012; Cotte and Trudel, 2009; Peattie, 2010). Academic work usually focuses on single countries. Few scholars have conducted cross-national research projects.

General population surveys and opinion polls suggest high levels of self-reported ethical consumption behavior in North America and Western Europe. In the first wave of the European Social Survey in 2002–03, for instance, around 40–50% of respondents from Scandinavia, Switzerland, Germany, the UK, and France indicated that they purchased products for political, ethical, or environmental reasons in the 12 months prior to the survey. Around 30% of Swedish, Swiss, British, and French respondents report to have boycotted products. Only 10–15% of respondents from Southern and Eastern European countries gave these answers (Koos, 2012; Yates, 2010). A 2010 survey in the United States found that around 50% of respondents indicated that they deliberately buy eco-friendly products (PEW Research Center, 2010).

These data need to be viewed with caution for two reasons: First, the high levels of self-reported buycotting behavior found in most general population surveys usually exceed the market shares of ethical products and services by far. For example, the Food and Agriculture Organization of the United Nations (FAO, 2009) reports that fair trade coffee – the oldest and most widely available fair trade product – accounts for less than 1% of the total European coffee market. In addition, market shares vary considerably between countries. For example, fair trade coffee accounted for 20% in the UK, 7% in France, 1% in Germany (Krier, 2008); U.S. market shares were at 3% in 2006 (Fair Trade Federation, 2008). Second, large-scale population surveys or market data might not always be appropriate to catch the complex actions and motivations of ethical consumers. These are generally omnibus studies (covering multiple topics), with just one or two items directly related to ethical consumer behavior. Thus, such research may be too insensitive to capture the 'ordinary' ethical consumers who (habitually) act in environmentally or socially sustainable ways and the 'ethical simplifiers' who pursue a lifestyle outside capitalist market societies.

Scholars have only begun to study ethical consumers in nonaffluent consumer societies as new middle classes with growing income levels and educational background gain momentum in emerging markets. Thus, studies on the propensity and motivations of ethical consumers in these countries remain scarce. Research on ethical consumption in Brazil and Chile (Ariztía et al., 2014), China (Gomersall and Wang, 2011), Poland (Koszewska, 2011), South Africa (Tustin and Jongh, 2008), and Turkey (Kirezli and Kuşcu, 2012), for example, suggests evolving segments of aspiring ethical consumers.

Historical Context

Lewis and Potter (2011) suggest that the rise and mainstreaming of ethical consumers in affluent societies at the turn of the twenty-first century represents a shift toward a "growing politicization of life and lifestyle practices" (p. 5) in mass consumer culture. However, ethical consumers are not exclusively of contemporary cultural concern. Historically, the two classical types of ethical consumer practices – boycotts and buycotts – date at least back to the eighteenth and the nineteenth centuries (Lewis and Potter, 2011: p. 6); and consumer boycotts focusing on economic objectives such as lower prices and higher quality products can be found as early as the fourteenth century (Klein et al., 2004). Prominent historical examples of social conflicts linked to consumer politics include the boycott of English goods by the Boston Tea Party in 1773 and the buycott of the White Label Campaign in 1899, when US women's consumer leagues rewarded department stores for their good labor conditions with a label (Lewis and Potter, 2011: p. 6).

Lang and Gabriel's (2007) analysis of the historical roots of ethical consumer movements identifies four waves: (1) the cooperative movement of English working-class people to meet their needs for high-quality and affordable food in 1844; (2) The value-for-money movement in the United States at the beginning of the twentieth century, which aimed at informing and educating consumers to get their money's worth; (3) 'Naderism,' named for Ralph Nader, the U.S. lawyer and consumer activist who dedicated his career to informing consumers of and empowering consumers against the alleged manipulation and systematic disinformation of consumers by businesses; and (4) Consumer concerns about the detrimental

impacts of affluent lifestyles on the environment appeared in the 1970s and 1980s. Forming a social movement in the 1990s, an increasing number of consumers expressed their disapproval of companies' environmentally harmful activities and refused to buy their products. A classic example of a consumer boycott motivated by perceived environmental abuse is the boycott of Shell gas stations in Germany in 1995 triggered by the company's plans to dispose the Brent Spar oil platform into the North Atlantic.

Since the 2000s, a broader ethical turn has linked ethical consumer practices to popular critiques of globalization and global social justice, overconsumption, materialism, and unsustainable lifestyles (Lewis and Potter, 2011: p. 7). Scholars discuss several reasons for the rise of ethical consumers (e.g., Harrison et al., 2007; Lewis and Potter, 2011; Newholm and Shaw, 2007; Stehr, 2008): increasing media coverage on the impact and risks of affluent lifestyles, state withdrawal from traditional areas of civic responsibilities with a subsequent upsurge of NGOs and new forms of civic participation, growing affluence and higher levels of education, long-term shifts from materialist values of basic needs to postmaterialist values of self-fulfillment and care for others, and expressing personal concerns and issues of self-image through consumption in today's consumer culture.

Approaches to Understanding Ethical Consumption and Ethical Consumers

The rise of ethical consumers and their practices in the everyday is matched by an increasing interest of scholars especially in the humanities and the social sciences. Since the beginning of the 2000s, researchers have published more and more academic work on the topic (Cotte and Trudel, 2009; Papaoikonomou et al., 2011). Key research questions cover a spectrum ranging from aspects of individualized ethical consumer decision-making, on one end, to structural and collective determinants of consumer movements, on the other end.

The philosophical basis of ethical consumption is a key research area within consumer ethics. Focusing on ethical consumption and ethical consumers in terms of personal moral conduct, scholars apply different philosophical theories to evaluate ethical consumption. Moreover, they discuss the meaning of 'ethical' and explore its dimensions of morality.

Scholars in business and marketing have focused on identifying and categorizing the ethical consumer. These empirical efforts began with profiling ethical consumers and establishing market segments based on sociodemographic variables (gender, income, education, etc.) and personality characteristics. However, as noted above, these findings proved to be unstable. Scholars hence moved on to the question of which factors determine individual ethical consumer practices.

Drawing on the concepts of attitudes, social psychologists have applied modified versions of the attitude–intention–behavior framework (mostly Ajzen's theory of planned behavior; TPB; Ajzen, 1991) to model ethical consumer practices. In most models of TPB, ethical consumption behavior is determined by the intention to perform this behavior, which in turn is influenced by corresponding attitudes and a subjective norm. Perceived behavioral control influences both, intentions and behavior (see Armitage and Connor, 2001 for a general meta-analytic review). Extended models of TPB include, for example, ethical obligation and self-identity as additional determinants (e.g., Shaw et al., 2000). Influenced by Schwartz's processual norm activation model (Schwartz, 1977) norms are again identified as key determinants of ethical consumption. Activated in a four-step decision-making process, it is the personal norm of feeling morally obliged to consume in an ethical manner that is to exert a positive effect on ethical consumption. It is assumed that in order to convert the moral obligation into actual behavior, the personal norm needs to be activated or formed – either as awareness of need (i.e., individual recognition that something needs to be done with regard to the situation at hand) or awareness of responsibility (i.e., individuals' recognition that they are responsible for doing something; see, for example, Guagnano, 2001 for an empirical application to recycled paper products).

Especially in research on green consumption, much scholarly work and discussion has concentrated on the effect of environmental concern as a general attitude toward pro-environmental consumption practices and whether its effect decreases as behavioral costs increase for consumers, the so-called low-cost hypothesis (Diekmann and Preisendörfer, 2003). Empirical evidence of the low-cost hypothesis is mixed, and the link between environmental concern and behavior is often found to be weak.

Economists who have examined the market shares of ethical products find that few consumers put their money where their mouth is, i.e., few actually go out of their way to implement their ethical concerns in the marketplace. Scholars and practitioners have discussed the gap between what consumers say (in surveys) and what they do (in the marketplace), known as the 'attitude–behavior gap' or 'ethical purchasing gap.' Some scholars argue that only improved theories will better account for the attitude–behavior link (see, for example, Carrington et al., 2010; Newholm and Shaw, 2007: p. 257f. with citations therein). Others argue that only better methods than conventional surveys will diminish the ethical purchasing gap (for more details see Section on Methodological Issues below).

Economists' standard approach to understanding consumer behavior focuses on consumers' willingness to pay (WTP) a premium for the ethical features of products. Concentrating primarily on product price and budget restriction, such studies assume that consumers choose the product alternative that gives them the highest expected utility per cost unit. Consumers reveal their preference in choosing the more expensive ethical product, and consequently, it is assumed that these consumers gain additional utility from the ethical attributes. Estimating consumers' WTP, researchers apply various forms of stated preference methods (e.g., contingent valuation, discrete choice experiments) and field experiments. Empirical evidence shows that consumers are indeed willing to pay an ethical premium, for example, for organic and fair trade products (see, for example, Rotaris and Danielis, 2011 and Papaoikonomou et al., 2011 and citations therein).

Identity theory in sociology informs a number of scholars of consumer behavior in analyzing ethical consumption. Drawing on the work of Bauman (1988) and Giddens (1991), who see consumption as an identity project central to the individual expression of self-meaning and the personal selection of

self-image in affluent societies of late modernity, studies find that ethical consumption can be considered as a means to express moral concerns and to construct a (consumer) identity as moral person.

Social scientists have also explored ethical consumption behavior in the context of conspicuous consumption, class, and distinction (Lewis and Potter, 2011: 13). Connected to the arguments of Veblen (1899) and Bourdieu (1984), that consumption practices can serve as a means to prove, retain, and reinforce social distinction and power structures in society, scholars discuss ethical consumer practices as elite projects of social distinction. Indeed, empirical evidence suggests that consumers with higher social status or higher class positions are more prone to ethical consumption (e.g., Johnston et al., 2011).

Human and cultural geographers have examined ethical consumption in the context of space and place (Lewis and Potter, 2011: pp. 13–16). Studies in this vein have focused on questions of commodity chains starting at the producer side of ethical consumption, caring at a distance, food miles, and, more recently, on the networks and organizations shaping ethical consumption (Clarke, 2008).

Criticizing the individualistic bias and the predominant model of ethical consumers as rational actors, scholars in geography and other disciplines argue that ethical consumption is primarily determined by macrolevel factors of networks, organizations, political regulations, and market structures that provide the infrastructure of ethical consumption, and less by factors on the level of individual ethical consumers.

Moving toward the other end of the spectrum, it is questions of civic engagement and collective action that point to the collective and contextual aspects of ethical consumption. Key issues in studies on political consumption and political consumerism evolve around consumption as voting and consumer sovereignty, consumer-citizenship and empowerment (Gabriel and Lang, 2006: Chapter 10), and individualized collective action (Micheletti, 2010). This perspective links ethical consumer practices to individuals' political concerns and serve as a means for political change beyond traditional approaches of political participation – potentially at the expense of (national) government responsibility or crowding out other means of political change that might be more effective. However, empirical evidence for these assertions is inconclusive. Normative concerns have also been raised that only the wealthy can afford to vote on ethical issues in the marketplace (Littler, 2011: p. 34). From a social movement perspective, (boycotting) campaigns of consumers or NGOs highlight the social dilemma of engaging individuals in the (costly) provision of public goods such as human rights, biodiversity, and animal welfare.

Methodological Issues

Scholars draw on a diverse set of methods to empirically investigate hypotheses about ethical consumers and their consumption practices. However, cross-sectional surveys predominate across disciplines as the sources of data that are used to address these hypotheses and gain insights into consumers' ethical purchase behavior, attitudes, and motivations. Cross-sectional surveys (of consumers or a general population) are subject to well-known methodological constraints. For example, simple item measures such as "When I go shopping, I prefer organic products" are typically found in these surveys. The drawback of such simple item measures is that respondents tend to overreport behavior they believe to be socially desirable. Some researchers apply qualitative approaches for data collection, such as in-depth interviews, focus group discussions, and content analysis, to reconstruct the social context of ethical consumers and their consumption habits. But social desirability bias can occur with in-depth interviews and focus group discussions as well.

Some researchers argue for study designs that provide respondents with incentives to uncover their 'true' attitudes, motivations, or behavior. Commonly, researchers recommend discrete choice experiments and contingent valuation methods as incentive compatible alternatives to standard population surveys. Likewise, lab and field experimental designs can be used to overcome biases in other data collection methods in order to study consumers' ethical purchase decisions (e.g., Cotte and Trudel, 2009; Devinney et al., 2010).

Critical Remarks

Along with the mainstreaming of day-to-day ethical consumers and the growing body of interdisciplinary research, scholars and practitioners alike have raised objections with how the field is conceptualized theoretically and practically.

Often, fault is found with the category of the ethical consumer itself. Just as the related term 'ethical consumption,' it is considered to be too inconsistent, too fragmented, and too ambiguous to be meaningful (e.g., Devinney et al., 2010; Littler, 2011). Many studies analyze only a small selection of ethical consumption practices; often it is the scholars who set the focus of research. Hence, researchers run the risk of missing the complex picture of consumers' ethical consumption strategies (Papaoikonomou et al., 2011: p. 213). In daily life, ethical consumer practices might contradict each other. For instance, European or North American consumers saving on food miles (i.e., avoiding food that is transported long distances from producers to consumers; Paxton, 1994) and at the same time buying fair trade products from faraway places (Littler, 2011: 28).

A second common objection raises the question of effectiveness: Can consumers change markets to be ethical? While proponents answer in the affirmative, critics consider ethical consumers to have only marginal influence in society. Some skeptics regard ethical goods as niche products unfit for the mass market, as a means for consumers to ease their guilty conscience, and as a means for companies to earn more profits by whitewashing or greenwashing. Devinney et al. (2010: p. 36), for example, find the image of the ethical consumer greatly exaggerated by activists. They exhort consumers to understand that only producers can change the moral conduct of markets.

A third objection points to the notion of ordinary consumers' habits being 'unethical' when contrasted with those of their ethical counterparts. Critics stress that many consumers frame their ordinary consumption in moral terms; an aspect, which is often neglected in popular and academic discourse on ethical consumption. From this perspective, focusing on ethical consumption solely in terms of highly visible consumer practices turns a blind eye on the less spectacular forms of

day-to-day consumption (Gronow and Warde, 2001; Lewis and Potter, 2011: p. 13; Newholm and Shaw, 2007: p. 260).

Avenues for Future Research

To advance the knowledge and understanding of ethical consumers and their practices, scholars need to address several gaps in research. First, future scholarly work would profit from a commonly accepted definition and typology of ethical consumers and their corresponding behavior. Second, an integrated theoretical framework of ethical consumer behavior would make it easier to study yet unresolved research topics (e.g., Newholm and Shaw, 2007; Papaoikonomou et al., 2011; Peattie, 2010). Future scholarship needs a solid theoretical basis to address the following questions: How does one become an ethical consumer and which factors shape this socialization process in different social groups? To what extent are ethical consumers embedded in their specific cultural and local context and are there cross-cultural similarities and differences? How are individual ethical consumers linked to collective projects of ethical consumption in families, households, and communities?

Third, acknowledging the plethora of ethical concerns and consumers' manifold motivations for their ethical practices, the need to draw on a variety of methods arises. Studying the same ethical consumption practice with different methodological approaches would allow more detailed empirical and theoretical analyses. At the same time, this strategy provides researchers with the opportunity to assess the extent to which their choice of methods influences the study of ethical consumers. Having the above mentioned research questions in mind, future scholarly work would also profit from more large-scale comparative and longitudinal studies to analyze the cultural context and socialization processes of ethical consumers. These need to be complemented with more in-depth qualitative studies to better understand the microlevel processes of ethical consumer practices.

Ethical Dilemmas, Research, and Access to Treatment

Dirceu B Greco, Federal University of Minas Gerais, Belo Horizonte, Brazil

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Rights and controversies of access to ethically sound clinical trials and right to universal access to established and new products of research are discussed. It is proposed the development of a comprehensive set of ethical requirements, with participation of government officers, international representative agencies, investigators, activists and civil society with an agenda to define where relevant clinical trials are to be performed, to adequately inform the prospective volunteers so that they can autonomously decide to participate and to ascertain posttrial access to developed products. Dilemmas in research ethics, including but not limited to access to care and treatment and the use of placebo will be dealt with and may then be settled.

There must be an internationally accorded decision on universal access to health care which will help guarantee the inclusion of the most prevalent illnesses, including orphan or neglected diseases, such as tuberculosis, malaria, leprosy, leishmaniasis, schistosomiasis, trypanosomiasis, better qualifying the original Millennium Development Goals. Universal access to health care implies the intensification in the fight to eliminate poverty, and as individuals/countries emancipate themselves it will help confirm that the status quo of inequality can be defeated. Dilemmas related to apparent scarce resources should be confronted with other funds, such as military investments and financial transaction taxes.

Introduction and Definitions

Universal access to quality care and treatment in a public health setting is an achievable human right. The ethics of conducting clinical trials are part of this. If clinical trials are conducted ethically has to be considered in relation to, the day-to-day difficulties of research involving vulnerable populations and countries.

The history of trials involving human subjects is blemished by many unethical experiments and the situation is not different in relation to access to decent health care throughout the world. It is fair to say that the interruption of the Tuskegee Syphilis Study (1932–72) was due to public outrage after news reports in 1972 in both the Washington Post and The New York Times. In this experiment there were "issues of race and racism, vulnerability of particular communities or populations, power, deception, exploitation, and questions about consent, appropriate study design and research hypotheses, distinctions between research and treatment, and standard of care" (Parker et al.; Fairchild and Bayer, 1999).

Other unethical trials were conducted in the US (Beecher, 1966; Hornblum, 1997) in the post-Second World War period and also outside the US – the Guatemala sexually transmitted diseases inoculation project is another hallmark of an unethical trial – (Reverby, 2011) after the issuing of Nuremberg Code (1947) and the then recently released Declaration of Helsinki – DoH (1964) (WMA).

The risks of unethical trials, probably not so deplorable as the ones mentioned above, were in part related to the exponential expansion in the last few decades of clinical trials originated in a developed but usually performed in developing countries (Macklin, 2004; Lavery et al., 2007).

The establishment of phase III efficacy trials, with thousands of volunteers and the globalization of the pharmaceutical industry facilitated the performance of these trials outside industry's country of origin. Add to that the easiness of recruiting participants in vulnerable environments, with possible laxer ethical requirements, with high burdens of disease and less demanding individuals, who many times see this participation as the only means of accessing medical care. On the other hand, more stringent rules in developed countries, where the participants' rights are at least formally protected, are part of the same picture, precluding the approval of some trials there.

Intellectual Background, Schools of Thought and Leading Advocates, Current and Emerging Directions

The necessity to protect research participants gave rise to the Nuremberg Code in 1947 (Shuster et al., 1997) and in the US to the Belmont report in 1979, the latter issued a few years after public disclosure of the Tuskegee study. In the Belmont Report three principles were included -autonomy, beneficence and justice, which according to the authors express the general values underlying rules in the common morality.

In 1979, Beauchamp and Childress (2001) helped consolidate a new phase for bioethics with the development of a theory of 'applied ethics,' known as the Principlism theory, which included the three principles of the Belmont report: autonomy, beneficence and justice, adding the forth principle of postmaleficence.

Principlism ethics has been mentioned in many documents, with critics arguing that it may not cover the whole spectrum of moral decisions. A thorough discussion of principlism is in Pierre Malia's Critical Overview of principles (2013), in Clouser and Gert (1990) and in Holms manuscripts (1996). Malia concurs with the great influence of Beauchamp and Childress in the development of bioethics, but argues that the principlism approach, "starting from American common-morality, leads to an underdevelopment of beneficence and justice, and that the methods offered for specification and balancing of principles are inadequate."

On the same token a Latin-American movement calls for 'an intervention bioethics' (Garrafa and Porto, 2003). The authors take in account what they understand as a "growing lack of political analysis of moral conflicts and of human indignation. The indiscriminate utilisation of the bioethics justification as a neutral methodological tool softens and even cancels out the seriousness of several problems, even those that might result in the most profound social distortions." Based on these premises, and on the concept that equity means 'treating unevenly the unequal,' they "propose a hard bioethics or intervention bioethics, in defence of the historical insights and rights of economically and socially excluded populations that are separated from the international developmental process."

Another bioethical approach, especially aimed at the destitute also originated in Latin America. Schram and Braz propose a Bioethics of Protection. According to the authors, this came in the scope of applied ethics in Latin America, related initially to the existing moral conflicts in Public Health in developing countries, combining the dialogue of consecrated bioethical tools and the context of the praxis of the Latin-American stakeholders. "To the traditional descriptive and normative functions of applied ethics, bioethics of protection proposes an additional function consisting in the 'protection' with priority of individuals and harmed groups, in order to permit them to develop, if possible, their capabilities, necessary to their empowerment, i.e., necessary to a decent life in a conflagrated world, and, possibly, searching for rational and/or reasonable solutions" (Schramm and Braz, 2008).

It becomes evident that the definition, principles, application and reason d'etre of bioethics is complex as the world we live in – multicultural, multilingual, with obscene disparities and violent.

Issues and Expected Changes

Here is one important dilemma- is it possible to keep the same exacting ethical standards independently of the origin, ethnicity or economic power of the volunteers?

My clear answer is Yes – origin, economic power, ethnicity must not be used to treat individuals with less rigorous ethical values, as we are dealing with human beings born with the same universal rights (Universal Declaration of Human Rights, 1948).

One of the risks of doing otherwise is the setting of double standards in clinical trials. And as access to care and common goods are not the same in different settings, not only in different countries but also within countries, performance of clinical trials in the developing and even with less well to do individuals in the developed world, carries the risk of cutting corners in ethical requirements and this actually has happened more often than not. Furthermore, unethical conduct is not limited to private pharmaceutical companies. Ethically fraught studies were also performed by foreign and local health agencies with the willing participation of local and international investigators (Reverby, 2011; Greco, 2013; Presidential Commission for the Study of Bioethics Issues, 2011).

It is many times mentioned that it is impossible to keep the same standards in poor environments and if research is not performed there these populations will be deprived of the progress of science. This is not a true dilemma as many of the trials performed in developing countries were not useful at all for their population. One example is the set of trials that occurred in the early 1980s to ascertain the efficacy of a vaccine against hepatitis B. They took place in both the developed and in a few developing world countries and showed that the vaccine was very effective. When commercially released its cost was not within reach of most countries. Even in 2000, the vaccine's availability in public health in Africa was limited to Botswana, Gambia, Mauritius, Seychelles, South Africa, Swaziland and Zimbabwe. Reasons listed for delayed introduction included high vaccine cost, weak infrastructure and low financing priority among donors (Arevshatian et al., 2007). Thus the question is not of performing health research anywhere for the sake of science but of doing relevant trials where volunteers can be adequately protected and when there is assurance of access to the research products to all that may need them – access in the sense of universal availability in the public health system.

There is another intertwined question: Health research is a broad term and search for knowledge is a human characteristic but the main objective of health research must of course be what above mentioned, that is provision of access to the efficacious products of research wherever needed.

If a vulnerable population/community/country has no condition for participating in a clinical research, the first perceived dilemma of precluding them of access to progress of science, is also counter argued with: first, that access to the products is more important than where the research is performed; second, if the specific research is of extreme value for this population and should be there performed, research conditions must be established locally prior to beginning of the trial.

Thus, inasmuch as clinical research trials with new medications or vaccines are undoubtedly necessary, they can be carried out only where independent ethical requirements and due evaluation is available, where risks of exploitation and double standards can be circumvented. Research must be designed and only implemented when the populations in which it is carried out stand to benefit from the results (CIOMS, 2002). Even with perceived and sometimes real urgency to search for better preventive methods, and more effective medications and vaccines, what is urgently needed is to have them available to all and not only to the trial participants. That will be dealt with in the treatment priorities dilemmas.

Thus the apparent dilemma of not performing a trial in certain circumstances is not an ethical dilemma as upon completion of the trial, if the product is shown to be effective, there should be international pressure to make it available (and affordable) wherever needed.

With this background two international documents, from UNAIDS and from WHO, listed circumstances/conditions in which biomedical research trials should not be performed. They include (UNAIDS, 2007; WHO, 2010):

- when the capacity to conduct independent and adequate scientific and ethical review does not exist;
- where voluntary participation and freely decided consent cannot be obtained;
- when conditions affecting potential vulnerability or exploitation may be so severe that the risk outweighs the benefit of conducting the trial in that population;

- when agreements have not been reached among all research stakeholders on access to medical care and treatment;
- when an agreement has not been reached on responsibilities and plans to make trial products (drugs, other treatments, or preventive measures) that prove to be safe and effective, available to communities and countries where they have been tested, at an affordable price.

Autonomy Dilemma

It has been argued that individual autonomy in trials can be limited for the sake of scientific progress. Yet often the relevance of the pursued knowledge is not well defined, or the expected results will not be relevant for this population. Moreover, many times trials are performed among vulnerable (social and/or economically) individuals/communities. Individual well being has to be prioritized against the value for the community (Rawls, 1971). To take one example: the AZT placebo-controlled trial among HIV infected women in Asia, Africa, and Central America in the 1990s. Participant's vulnerability was clear as they came from a poor environment, had difficulty in understanding the informed consent terms, had limited access to adequate health care, making them prone to participate in a trial just to receive medical care. In 1997, a strong editorial by Marcia Angell (1997, 2000) and a paper by Lurie and Wolfe (1997) in the same issue of the New England Journal of Medicine criticized the ethics of these studies performed outside the US. A shorter scheme of AZT, eliminating its intravenous use was tested not against the gold standard ACTG 076 (MMWR, 1995) but against placebo instead. Angell questioned if these trials were not reminiscent of the Tuskegee study. This editorial and article brought about fierce discussions that ensued strong pressure from US investigators and agencies to change the 1996 version of the World Medical Association (WMA) Declaration of Helsinki (DoH), at that time the most internationally respected set of ethical guidelines on human research. Their intent was to modify two articles, exactly those dealing with access to best proven medical care to all trial participants and with restrictions on placebo use when an efficacious treatment exists. Pressures were overwhelming and WMA backed off adding two notes of clarification, making it easier to dodge requirements of treating participants with respect and rights irrespectively of their origin or economic power, setting grounds for double standards in clinical research. The item on Placebo use, that in the 1996 version was not permitted when an efficacious control was available, has been changed and the 2013 version confirmed the possibility of its use even in certain circumstances where an efficacious control exists. This is an example of how guidelines may not be in the best interest of developing countries and to counteract this situation, countries have autonomy to be more stringent in protecting clinical trials participants. This was the case in Brazil: the National Research Ethics Commission (CONEP) in its Resolution 466/2012 (Conselho Nacional de Saúde (CNS) Brasil, 2012), which regulates all Brazilian human research states on the use of placebo: "Benefits, risks, burdens and effectiveness of a new method should be tested against those of the best current prophylactic, diagnostic, and therapeutic methods. This does not exclude the use of inert placebo in studies where no proven diagnostic or therapeutic method exist." On the same token the Brazilian Federal Medical Council (Conselho Federal de Medicina (CFM) Brasil, 2010) in the 2010 version of the National Code of Medical Ethics considered unethical for any physician to participate in a research project where placebo is used in the control group when there are efficacious and effective drugs for the disease being tested. And more recently the Latin American and Caribbean Medical Confederation in their XVI General Assembly convened in 2013 in Pachuca, México issued the *Declaracion de Pachuca* (Confederacion Medica latinoamericana y del Caribe, 2013), where it unanimously rejected any human medical investigation utilizing placebo when there is an efficacious drug for the disease being studied. They also propose that governments should neither authorize nor finance drugs that used placebo for their evaluation when a proven control existed.

Safeguarding against Exploitation

There are procedural ways to partially curtail vulnerability issues that may occur in clinical trials. For example, establishment of an internationally approved and enforceable research ethics document, with guidelines based on human rights aimed at universal access to decent health care, plus the availability of publicly disclosed research proposals and results. With this in place studies such as Tuskegee, Guatemala, the AZT trials for infected mothers performed in the late 1980s and many other not as (in)famous that occurred in many countries will never be permitted again.

It will of course be more difficult to overcome the hurdles to achieve the much-needed fundamental changes. Who and where are (and should be) the real stakeholders? The real stakeholders are all individuals who can use the results of good science. Of course this may sound vague but it means that is possible to involve individuals, communities, public health officers and the research team in decisions related to relevant clinical trials so that efficacious products are made available in the public health settings.

In this direction the following points, modified from UNAIDS 2004 Guidance document (UNAIDS, 2004) should be considered:

- All stakeholders including individuals, communities, public health agencies and officers, and the research team, both from developed and developing countries, should collaborate during all stages of the study, from the development of the protocol to the publication and application of the results in public health to all who need them. The response to the AIDS epidemic may be used as a good example of this broad involvement.
- Decisions about access to the products which result from the studies should be made based upon the principles of justice, meaning that those who have to cope with the heaviest burden should receive the appropriate benefits. Participants must have posttrial access to drugs, vaccines, interventions, prevention strategies and any other benefits resulting from the study.
- The involvement of international representative agencies (such as UN/WHO) will be a crucial asset to universalize access.

- Financing of studies should include funds for strengthening local capacities, not only those related to the specific aims of the project, but also local infra-structure, institutions and host country capacity to conduct research projects.
- It is extremely important to deepen the discussion on the informed consent process. Such consent must be obtained in ways that respect the dignity and cultural values of the volunteers.
- Inclusion of vulnerable individuals shall warrant special justification and appropriate protection and should occur only when the aim of the project is to their own benefit.

Social Determinants, Power Relations, and Emancipation

To confront disparity, exploitation and poverty there is no place for the so-called *empowerment*, which supposedly means that someone is going to transfer power to someone else, does not hold true. Empowerment is supposed to 'give' capacity to individuals in relation to their needs and expectations. Unfortunately, this is a figure of rhetoric as power is never given, very seldom shared. Most of times it means a top down way of marginally providing a little to those in need, to calm down their claims. These vulnerable individuals/countries will praise the 'donors' for helping them get what is nothing more than their rights. This only perpetuates dependency, in a new sort of colonialism – Give the rings, save the fingers and maintain the status quo of disparity and vulnerability.

What is here proposed is *emancipation* in the sense proposed by the Brazilian educator Paulo Freire. Writing on education for freedom, Freire held that human liberation will neither occur accidentally nor as a concession, but it will be a conquest of human praxis, demanding constant fighting to have it achieved. In Freire's method there is a moment when the oppressed take the nitiative to fight and emancipate themselves from the oppressors (Freire, 2005). Thus, emancipation goes hand-in-hand with access to education, citizenship, human rights and the confrontation of disparity.

Ethics of Universal Access to the Products of Research and to Adequate Health Care (Universal Health Access)

Access to the Products of Research – Political Decision + International Participation

Even with a well-established research ethics framework, access to the developed products, that is, making them available and affordable is getting increasingly complex. Despite possible political and budgetary commitment, costs of new, more complex and patent-protected medications are straining health available resources worldwide. Thus there is an urgent need for decreasing these costs and this may happen, for instance, through international collaboration in procurement. Examples include the Pan American Health Organization (PAHO) Strategic fund, UNITAID and Clinton Health Access Initiative (CHAI).

PAHO's strategic fund is a cooperation mechanism to improve access to and supply management of strategic public health supplies. As a procurement mechanism, it allows participating members to utilize a common fund for payment of authorized purchases of essential public health commodities. The Fund is capitalized through the allocation of the 3% procurement service charge. As more countries participate, the purchasing power of the Fund is expected to increase resulting in lower product prices (PAHO).

UNITAID was launched in 2006 at the opening of the 61st Session of the General Assembly of the United Nations by Brazil, France, Chile, Norway and the United Kingdom It uses innovative financing to increase access to treatments and diagnostics for HIV/AIDS, malaria and tuberculosis in low-income countries. A novel way of financing UNITAID was established through a small levy on airline tickets in several countries. As of the end of 2011, this levy has collected US $1.06 billion – 66% of the US $1.6 billion raised by UNITAID.

The CHAI was established in 2002 addressing the HIV/AIDS crisis in the developing world and aiming at strengthening local health systems. CHAI "works to improve markets for lifesaving medicines and diagnostics, lower the costs of treatments, and expand access to life-saving technologies" (CHAI).

These mechanisms should be associated with national or regional political decision to implement local production of generics, WHO pre-qualified, at fair prices to counteract the ever increasing costs of patent medicines. There are legal tools for issuing compulsory licensing of drugs to protect public health, in accordance with TRIPS allowed flexibilities (Declaration on the TRIPS agreement and public health; Greco and Simao). It must be added that a substantive part of the costly research on several drugs were and still are occurring in universities and research institutes financed mainly by public funds in the US and Europe, which must also be brought to the global discussion on patents, transfer of technology and price setting.

Access to Adequate Health Care (Universal Health Access)

Universal access to good quality healthcare is *sine qua non* for achieving real distribution of research results. To reverse the current situation, intense changes in the world order will be necessary to attain fair distribution of resources, equity and to decrease vulnerability of all involved. The dilemma here perceived is that the status quo of access and funding for health is scarce and it is not possible to change that. One counterargument used by many concerned with access to adequate health care, is that funding for all disease-related expenses should be weighed against other uses of public monies and holds that funding for health should be increased by decreasing the budget for military purposes.

To help discuss the apparent dilemmas in relation to access to funding for health care, the AIDS epidemic is a very special example. Much has been written about the enormous economic burden of the AIDS epidemic, including direct (medication, out-patient care, hospices, hospitalization), indirect (research, education, prevention, loss of GNP) and social costs for the individual, their communities and countries (Mann, 1987). It must be remembered that in most of the third world, HIV infection is added to a list of diseases already endemic (e.g., schistosomiasis, Chagas, leishmania, hepatitis, malaria, leprosy). It is also true that even in developed countries access to decent and affordable health care is not universal (Stillman, 2013).

In 2013, Piot and Quinn (2013) and Brandt, (2013) underlined the important role of the AIDS epidemic in shaping global health, even with all the suffering the epidemic

imposed to millions of individuals. Pressure from society and also from the disease itself may be strong enough to modify these 'fixed budgets.' To better illustrate the skewed distribution of available funds the 2013 report of the Stockholm International Peace Research Institute (SIPRI) estimated that world military spending in 2012 was $1.75 trillion, of which $682 billion were spent by the US, $166 billion by China and $90.7 billion by Russia. There was increased spending in Asia, Eastern Europe, the Middle East, North Africa and Latin America. Military expenditures were several hundred times WHO's annual budget of $395 billion for the 2012–13 period for all their programs. It is also several hundred times higher than the annual budget of the US Centers for Disease Control (CDC) of over $10.0 billion, and the Gates Foundation, which in 2012 donated $1.3 billion to the Global Fund to Fight AIDS, Tuberculosis and Malaria (Chelala, 2013). To change this distribution is of course difficult and complex but worth pursuing. More recently a movement was set in motion aiming at finding resources from other available sources by establishing a Financial Transaction Tax (FTT) for Global Health. It is estimated that the 2008 economic crisis has put an extra 200 million people, which had nothing to do with the reasons for the crisis, living on less than $2 a day in some of the world's poorest countries (Oxfam, 2010). On the other hand, the financial sector was and has been bailing out and is continuing to make huge profits. This FTT could make banks, hedge funds and other parts of the financial sector pay their fair share to cover for what was their responsibility and provide long term financing for global health, to help attain the Millennium Development Goals (MDGs) (2000). An FTT even with an average tax of just 0.05% on transactions (such as bond and share sales) could raise as much as $409 billion a year (Leading group on innovative financing to fund development, 2010).

Conclusions/Perspectives

Unfortunately, health disparities will not be solved just by standards and guidelines that regulate research and researchers; not even exclusively by treating everyone as equals in studies involving human beings.

Justice and thus, equal access to treatment and care, will be served when individuals, communities and countries emancipate themselves to fight for their rights. In his *History of the Peloponnesian War*, Thucydites (411 BC) wrote that Justice would prevail when those who are not subjected to injustice are as indignant as those who are. I dare counter with the following: Justice will only prevail when those affected by injustice emancipate themselves to fight for their rights. Making sure that equity is respected in clinical research is of course a step toward reversing the current injustice in the allocation of resources for health research and can contribute to the emancipation of volunteers, researchers and society, to fight for their rights as citizens.

Perspectives for Ethics in Research

A concerted action of governments, international representative agencies, investigators, activists and civil society will be crucial to develop together an agenda to define where relevant clinical trials are to be performed, how to prepare the sites for these trials, to adequately inform the prospective volunteers so that they can autonomously decide to participate and to ascertain posttrial access to the developed products.

A comprehensive and harmonized set of ethical requirements must be developed, ideally under the umbrella of WHO and UNESCO. This requirements could use established international documents, such as Universal Declaration on Bioethics and Human Rights (UNESCO, 2005) and the CIOMS International ethical guidelines for biomedical research involving human subjects (CIOMS, 2002). These world representative institutions could convene a multinational, multidisciplinary working group, including civil society to elaborate and open up for discussion a draft document of ethical requirements based on human rights and equity. Dilemmas in research ethics, including but not limited to access to care and treatment and the use of placebo will be dealt with and may then be settled. This document should be broad enough to encompass a road map for universal access to the developed efficacious products. This will be a daunting but worthwhile task to really and truly convince the world that access to health is not a commercial commodity but a human right, that progress in research and development must be available to all, and must be shared throughout the world.

Perspectives for Universal Access to Health Care

It must be noted the recent decision at the United Nations 67th General Assembly on Universal Health Coverage (GA December 2012). A consensus text was adopted encouraging member states to plan and pursue transition of national health care systems toward universal coverage (UN 67th General Assembly, 2012). This is in accordance with the International Covenant on Economic, Social and Cultural Rights directives on rights to the highest attainable standard of health (UN ECOSOC, 2000). Examples of public health access, such as the universal public health systems of Brazil, Canada and UK, confirm that it is attainable and feasible in different settings.

As already mentioned, AIDS can and should be used as a global health example with a multipronged and multidisciplinary involvement of all stakeholders, including health authorities/governments, sponsors, scientists, and civil society (Brandt, 2013; Piot and Quinn, 2013). The decision on universal access to health care will help guarantee the inclusion of other (orphan or neglected) diseases with much less clout but as significant and disseminated as HIV/AIDS, including, but not limited to, tuberculosis, malaria, leprosy, leishmaniasis, schistosomiasis, trypanosomiasis, better qualifying the original Millennium Development Goals.

More importantly universal access to health care implies the intensification in the fight to eliminate poverty, and as individuals/countries emancipate themselves it will help confirm that the status quo of inequality can be defeated.

Ethical Guidelines and Codes of Conduct in Social and Behavioral Research

Thomas L Van Valey, Western Michigan University, Kalamazoo, MI, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article briefly reviews the situation regarding research ethics in Australia, Canada, Great Britain, and the United States. It notes some of the areas where regulations referring to social/behavioral research are similar, as well as areas where they differ. It then turns to the codes of ethics of various professional organizations, first describing them and then comparing and contrasting them. Finally, it points to the future of social/behavioral research and the emerging trend toward broader notions of research integrity and the responsible conduct of research.

Introduction

The guidelines and codes of conduct that exist today have essentially been created in response to major incidents, mostly in the area of medical/health research with human subjects that became highly publicized. They can certainly be traced directly back to the Nuremberg Code (1949) and the Declaration of Helsinki (1962). In the United States, the Belmont Report (1979) built upon these documents, and in turn, became the basis for what has come to be known as the Common Rule (1981), which applies wholly or in part to most federal agencies. In addition, many academic institutions accept the Common Rule as the basis for their own institutional policies, whether they receive federally funded research or not.

While the original focus of most regulations was on medical/health research and the protection of human subjects from physical harm, other well-publicized incidents resulted in social and behavioral research being included (Coleman et al., 2005). Nevertheless, although they apply to the social and behavioral sciences, most of the current regulations and guidelines dealing with human subjects continue to focus on issues most relevant to medical/health research. For this reason, some tensions exist in the regulatory context. These tensions tend to revolve around methodological issues (e.g., qualitative and other approaches seldom used in the health/medical areas) and/or substantive issues (e.g., topics that often produce controversial viewpoints, such as crime, poverty, and human sexuality).

In recent years, emphasis has begun to extend beyond the protection of human subjects (and animals) in research to the broader notions of research integrity and the responsible conduct of research (RCR). While it includes the protection of human subjects, RCR also covers such things as conflicts of interest, data management, authorship, and safety issues. With some exceptions, this article will deal primarily with the guidelines and codes of conduct relevant to the use of human subjects in research, and less with other dimensions of professional activity.

Regulatory Contexts

Australia

In Australia, the *National Statement on Ethical Conduct in Human Research* (2007) and the *Australian Code for the Responsible Conduct of Research* (2007 – referred to as the Research Code) are the primary sources for regulations and guidelines. Australia has established Human Research Ethics Committees that review proposed research projects. The Australians have identified a set of four principles upon which reviews are based:

1. Integrity
2. Respect for persons
3. Beneficence
4. Justice

The Research Code provides a framework for responsible research practice and lays out guidelines in data and record management, publication of findings, authorship, conflicts of interest, and other areas (http://www.nhmrc.gov.au/book/national-statement-ethical-conduct-human-research).

Canada

In Canada, the fundamental regulations and guidelines that apply to all research – including health, humanities, natural and social sciences, and engineering – is the *Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans*. The first edition was produced in 1998 and was revised in 2010. For the social and behavioral sciences, this is primarily the purview of the Social Sciences and Humanities Research Council of Canada, the major funding source. In addition to the Tri-Council Policy, Canadian government-funded researchers and their institutions must also follow other policies pertaining to research integrity, peer review, and conflicts of interest. Numerous other research organizations in Canada have adopted the Tri-Council Policy as the basis for their own operations. (The full text of the statement is available at http://www.ethics.gc.ca/pdf/eng/tcps2/TCPS_2_FINAL_Web.pdf)

The three core principles underlying the Canadian Tri-Council Policy are:

1. Respect for persons
2. Concern for welfare
3. Justice

Research Ethics Boards (REBs) are the entities charged with the actual reviews of proposed research. The REBs are created and maintained by the institutions that have jurisdiction over human research.

The United Kingdom

In the United Kingdom, the responsible regulatory bodies are the National Research Ethics Service and the Economic and Social Research Council. For the social and behavioral sciences, the *Framework for Research Ethics* provides the basic principles and guidelines. It was first published in 2005 and revised in 2010 and again in 2012 (it is available at http://www.esrc.ac.uk/_images/Framework-for-Research-Ethics_tcm8-4586.pdf). The *Framework for Research Ethics* explicitly identifies six principles that should be addressed in any review of proposed research:

1. Research should be designed, reviewed, and undertaken to ensure integrity, quality, and transparency.
2. Research staff and participants must normally be informed fully about the purpose, methods, and intended possible uses of the research, what their participation in the research entails, and what risks, if any, are involved.
3. The confidentiality of information supplied by research participants and the anonymity of respondents must be respected.
4. Research participants must take part voluntarily, free from any coercion.
5. Harm to research participants and researchers must be avoided in all instances.
6. The independence of research must be clear, and any conflicts of interest or partiality must be explicit.

In the United Kingdom, the reviews of research are carried out by Research Ethics Committees, according to procedures established by the organizations that sponsor the research.

The United States

In the United States, the Common Rule (originally established in 1981) is the basic set of regulations and guidelines, primarily aimed at the treatment of human subjects in research. As such, it was one of the first sets of regulations and guidelines established, following public and political outcries over such incidents as the Tuskegee syphilis study (1932–72), and human radiation experiments (1944–74), along with the Milgram experiments on obedience (published in 1963), and the Zimbardo prison experiment (which took place in 1971). The National Research Act of 1974 created the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research which was charged with developing guidelines for the protection of human subjects in research. That commission produced the Belmont Report (1979), which identified three fundamental ethical principles:

1. Respect for persons
2. Beneficence
3. Justice

These principles continue to serve as the basis for the ethical reviews of research in the United States (http://www.hhs.gov/ohrp/humansubjects/guidance/belmont.html).

It was also as a result of the National Research Act of 1974 that Institutional Review Boards were mandated, initially for those institutions with federally funded research, but now more generally. Although there have been a number of subsequent bioethics commissions, the 1974 commission that produced the Belmont Report is generally regarded as being the most influential. Today, the Office for Human Research Protection, within the Department of Health and Human Services, has the primary responsibility for enforcing the Common Rule (The Common Rule (45 Code of Federal Regulations 46) is available at http://www.hhs.gov/ohrp/humansubjects/guidance/45cfr46.html).

In addition to the protection of human subjects, the United States also supports a separate agency – the Office of Research Integrity (ORI) – for the detection, investigation, and prevention of research misconduct. ORI was created, in 1992, as a result of congressional hearings on cases of research misconduct that occurred in the late 1970s and early 1980s. According to the federal regulations, research misconduct is defined as "fabrication, falsification, or plagiarism in proposing, performing, or reviewing research, or in reporting research results…." While fabrication is the use of made-up data or results, falsification is defined as the changing or omitting data or research processes. Plagiarism is defined as the wrongful appropriation of another author's research or ideas. However, research misconduct does not include honest errors and differences of opinion (http://ori.dhhs.gov/federal-research-misconduct-policy).

Since 2000, the role of ORI has expanded beyond the detection and investigation of research misconduct within the Department of Health and Human Services. Today, it is also actively engaged in a program of research and education designed to promote the RCR and research integrity.

Comparison of Regulatory Contexts

These various regulations dealing with the protection of human subjects differ primarily in the details of the approaches they use to address the public responsibility that governments have toward the protection of their citizens. For example, they use different names to refer to their review committees, and the composition and specific activities of those committees vary from country to country. They also differ somewhat in the extent to which their regulations go beyond the protection of human subjects to the RCR. For example, Australia has a separate document relating to RCR, and elements of RCR are present in the Canadian and United Kingdom documents (e.g., confidentiality, conflicts of interest). In contrast, in the United States, this function falls under separate regulations, and is under the auspices of an entirely separate agency.

The regulatory contexts for social/behavioral research are similar in that they all have origins in Nuremberg and Helsinki. Moreover, there is an extraordinary degree to which the government regulations referring to social/behavioral research are similar. All of them are based on sets of core principles, most of which are either identical to or resonate with the Helsinki Declaration or the Belmont Report (e.g., Justice, and Respect for Persons in the United States, Canada, and Australia). All underscore the need to avoid doing harm to the people who are asked to participate in research, and to get their voluntary consent to participate. Also, all call for the creation of entities (i.e., ethics review committees) to review research proposals that involve human subjects. In addition, in each country, these

review committees are also highly decentralized, being located in each institution that supports research activities.

In sum, the regulatory contexts of all four governments reviewed, and indeed, much of the European Union, are remarkably consistent in their basic form and structure. It is in the specificity of definitions and operations where they differ. Thus, researchers seeking to carry out their research cross-nationally must use extreme care to make sure that they do not inadvertently violate regulations that are different from the ones to which they are accustomed.

Major American Social and Behavioral Professional Associations

American Psychological Association

The document, *Ethical Standards of Psychologists*, was first published in 1953. Since then, it has been amended 11 times, most recently in 2010, and is now titled *The Ethical Principles of Psychologists and Code of Conduct* (http://www.apa.org/ethics/code/index.aspx). It has an introduction, a preamble, a set of general principles, and a number of ethical standards. The document explicitly states that the preamble and general principles are aspirational in nature. The five general principles are as follows:

1. Beneficence and nonmaleficence
2. Fidelity and responsibility
3. Integrity
4. Justice
5. Respect for people's rights and dignity

In comparison, the ethical standards are to be considered by psychologists as enforceable rules of conduct. There are 10 Ethical Standards, each with multiple subsections. They cover a wide range of professional topics, including privacy and confidentiality, record keeping and fees, research and publication, education and training, assessment, and therapy.

The American Psychological Association (APA) maintains an Ethics Office. "The APA Ethics Office has five primary roles: to adjudicate ethics complaints; to provide ethics education; to assist the association in developing policies related to the Ethics Code; to promote the presence of, and interest in, ethics throughout the APA membership and governance process; and to offer consultation on ethics-related questions" (Behnke, 2007). As part of its responsibilities, the Ethics Office cooperates with the Ethics Committee in making judgments on complaints. It also supports members and the association in dealing with ethical issues and provides consultation. Lastly, the Ethics Committee offers workshops and seminars on ethical standards (http://www.apa.org/ethics/).

The Ethics Committee is given the responsibility for recommending rules and procedures for its operation, as well as executing investigations of unethical conduct by members of the APA. While the Committee may dismiss an allegation of unethical conduct, it recommends other actions (e.g., censure, expulsion) to the APA Board of Directors. There are two types of investigations typically carried out by the committee: (1) show cause proceedings – where formal action has previously been taken by another body (e.g., a felony conviction); and (2) complaints alleging violations of the ethics code that may be brought either by individuals or by the Ethics Committee itself.

With regard to complaints of unethical conduct, a preliminary evaluation is first undertaken to determine if the respondent (i.e., the subject of the complaint) is a member of the APA (which is required), and if the complaint has been submitted correctly. If a case is opened, the Director of the Ethics Office issues a charge letter to the respondent and conducts an investigation. The respondent is able to comment on all information to be considered by the committee. The Ethics Committee reviews all of the materials and decides how the case will be resolved. The Committee can dismiss the complaint, recommend reprimand or censure, recommend that the respondent resign from the APA, or recommend expulsion. In certain instances, the respondent has the right of appeal, which may include an in-person proceeding before a formal hearing committee (http://www.apa.org/ethics/code/committee.aspx).

American Sociological Association

The *Code of Ethics* of the American Sociological Association (ASA) was initially approved by its members in 1971. In the early years, as it was in the nation at large, ethical behavior in the conduct of research was the focal issue. Over time, a much wider range of ethical issues were recognized as relevant to a Code addressing the professional conduct of sociologists (The full text of the ASA Code of Ethics and the policies and procedures for the Committee on Professional Ethics (COPE) are available on the ASA web site at http://www.asanet.org/about/ethics.cfm).

The development of the code began with the first ad hoc committee on professional ethics, which was created in 1961. However, there was opposition within the membership to the establishment of a formal ethics code, and the project was shelved (Rhoades, 1981). Another ASA committee was appointed in 1967, and it prepared a draft that focused largely on the conduct of research. That initial version of the Code was approved by the ASA membership in 1969, but it was not operational until 1971 when the ASA had completed the task of establishing the procedures for the enforcement of the Code. Since 1971, the Code has been revised four times. The major changes increased attention to the ethical situations presented by the employment of sociologists in government as well as in for-profit and nonprofit organizations, and a section was added on fair employment practices. Revisions to the COPE policies and procedures focused on ensuring the confidentiality of the complaint process and underscored the degree to which mediation should be initially employed in the resolution of complaints.

The current version of the Code was approved by the ASA membership in 1997. It includes an introduction, a preamble, and five general ethical principles:

1. Professional competence
2. Integrity
3. Professional and scientific responsibility
4. Respect for people's rights, dignity, and diversity
5. Social responsibility

These principles of ethical professional conduct are expressly aspirational. They underlie the 20 specific ethical standards (many of which contain multiple subsections) that

are the enforceable standards of ethical conduct for sociologists. The enforcement of the Code through COPE applies only to current members of the Association. In becoming a member, individuals explicitly agree to adhere to the Code's ethical standards and can thus be held accountable. If an ASA member's conduct is determined to have been unethical under the Code, the sanctions available to COPE include: a private reprimand (that may include an action to rectify a wrong); a public reprimand; denial of privileges; and termination of membership for a given period of time (Kennedy, 1996).

At the ASA, the full-time Executive Officer of the Association is the liaison to COPE (although this duty may be delegated). COPE procedures explicitly call for the Executive Officer to attempt to resolve complaints before initiating a formal investigation. In recent years, the ASA has typically received an average of about 20 inquiries annually. Most involve interpretations of the Code or allegations concerning individuals who are not members of the Association. The few remaining are mostly about issues that the Executive Officer or the chair of COPE can respond to informally, and mediate without a full investigation by the committee. During a recent 5-year period, only one official complaint proceeded through full investigation and decision, and this frequency is not unusual. (The material describing the ASA Code and its enforcement are largely drawn from Van Valey and Hillsman, 2007.)

American Anthropological Association

Statement on Ethics: Principles of Professional Responsibility – the ethics code of the American Anthropological Association (AAA) was first published in 1971. Subsequent revisions were published in 1998, 2009, and most recently, in 2012. The document contains a preamble and a set of seven core principles:

1. Do no harm.
2. Be open and honest regarding your work.
3. Obtain informed consent and necessary permissions.
4. Weigh competing ethical obligations due collaborators and affected parties.
5. Make your results accessible.
6. Protect and preserve your records.
7. Maintain respectful and ethical professional relationships.

Each of the principles is accompanied by a brief discussion and link to other resources. The AAA preamble states, "…these principles are intended to foster discussion, guide anthropologists in making responsible decisions, and educate." Consequently, the AAA does not have a mechanism for enforcing its code of ethics (http://www.aaanet.org/profdev/ethics/upload/Statement-on-Ethics-Principles-of-Professional-Responsibility.pdf).

International Sociological Association

The International Sociological Association's (ISA) Code of Ethics includes a preamble and four sets of specific ethical standards to which all members of ISA must adhere (http://www.isa-sociology.org/about/isa_code_of_ethics.htm).

The code was approved in 2001, and the four standards are:

1. Sociology as a field of scientific study and practice
2. Research procedures
3. Publication and communication of data
4. Extra-scientific use of research results

Each of these standards has several subsections. The specific goals of the Code of Ethics are to protect individuals and groups that are in involved in sociological research, and to provide a framework for the research of ISA members (http://www.isa-sociology.org/about/isa_code_of_ethics.htm).

Other Academic and Professional Organizations

Many other academic and professional organizations in the social sciences also have codes of ethics. Of those, most appear to have used either the code of the APA or the code of the ASA as a model (e.g., the Association for Applied and Clinical Sociology). For example, among the regional sociological associations in the United States, the North Central Sociological Association has adopted a version of the ASA code produced by its Committee on the Profession, Freedom, and Responsibility. Others, rather than writing or adapting their own, have taken the position that their members will simply abide by the ASA code (e.g., the Pacific Sociological Association, and the Midwest Sociological Association). Some of the regional sociological associations (e.g., the Southern Sociological Society, the Eastern Sociological Society) do not have explicit codes of ethics. However, they do have committees in place that consider issues of an ethical nature. Nevertheless, with the exception of the ASA itself, none of the other sociological associations have active enforcement procedures in place.

Comparison of Professional Codes of Ethics

It is first apparent that most American professional associations in the social and behavioral sciences do have a code of ethics or some functional equivalent. Indeed, many of them are quite similar in form and even in content. It is also clear that the codes of ethics maintained by these professional associations are far less concerned with the treatment of human subjects than the governmental regulations. While they do adopt (or at least adapt) ethical principles similar to those expressed in the Belmont Report, there is clearly more attention paid to a much wider range of professional roles and behaviors. In each case, there are standards (or statements, as in the AAA) that deal directly with research activities, such as informed consent, respect for people's rights, and the research record. However, there are many more that cover other interpersonal contexts such as exploitation, harassment, and conflicts of interest, as well as professional activities such as teaching, authorship, publication, plagiarism, and clinical or applied work, both in and out of the workplace. This, of course, is to be expected, since the nature of professional associations is to focus on the full range of professional activities and responsibilities carried out by their members.

It is notable that the APA and the ASA are the only major professional social/behavioral science associations with an enforcement process that allows members and others to submit a charge of unethical behavior about a member. In both cases,

it is gratifying that the process is relatively infrequently used. However, also in both cases, there is substantial infrastructure support required. In each case, an organizational officer and a number of members are required to deal with the inquiries and allegations that take place. While most of the support is in the form of the time expended by these people, there are also record keeping, communications, and logistic needs as well.

The governmental process most comparable to code enforcement by professional associations is the detection and investigation of research misconduct by ORI. Yet, the vast majority of infractions reported by the professional associations deal with matters other than research misconduct, while research misconduct was the primary purpose for the creation of the government agency.

The Responsible Conduct of Research

In 2010, at the 2nd World Conference on Research Integrity held in Singapore, a statement on research integrity was established. As an attempt to establish common principles and responsibilities that extend across all research, a set of 4 fundamental principles and 14 responsibilities were agreed upon – *The Singapore Statement*. As its Preamble states, "While there can be and are national and disciplinary differences in the way research is organized and conducted, there are also principles and professional responsibilities that are fundamental to the integrity of research wherever it is undertaken." (The full text and related materials are available at http://www.singaporestatement.org/statement.html.)

The Singapore Statement identifies four fundamental principles:

1. Honesty in all aspects of research.
2. Accountability in the conduct of research.
3. Professional courtesy and fairness in working with others.
4. Good stewardship of research on behalf of others.

In addition, it lays out 14 responsibilities that are necessary to the integrity of research, regardless of where it takes place:

1. Integrity – insure the trustworthiness of research.
2. Adherence to regulations – be aware of and adhere to regulations and policies.
3. Research methods – use of appropriate methods, critical analysis of data, fully and objectively report findings.
4. Research records – clear and accurate, to allow replication and verification.
5. Research findings – share data and findings.
6. Authorship – include only those who meet applicable criteria.
7. Publication acknowledgment – acknowledges others who make contributions but who do not merit coauthorship.
8. Peer review – be fair, prompt, and vigorous, while respecting confidentiality.
9. Conflict of interest – disclose financial and other conflicts that could compromise the trustworthiness of the work.
10. Public communication – limit public communications to areas of expertise.
11. Reporting irresponsible research practices – notify appropriate authorities.
12. Responding to irresponsible research practices – develop procedures for responding to allegations, as well as protecting those who report them.
13. Research environments – encourage integrity through education, policies, and reasonable standards for advancement.
14. Societal considerations – weigh societal benefits against risks.

While *The Singapore Statement* clearly goes well beyond the ethical treatment of human subjects in research, it does identify the direction that ethical guidelines and codes of conduct are moving, not only for the social and behavioral sciences, but also for research in general. The 3rd World Conference on Research Integrity was held in Montreal in May 2013, and as a result issued *The Montreal Statement on Research Integrity in Cross-Boundary Research Collaboration*s (http://wcri2013.org/Montreal_Statement_e.shtml). This document focuses on issues central to cross-national and cross-disciplinary research, and moves the conversations regarding research ethics and the RCR even more broadly than *The Singapore Statement*. The 4th World Conference on Research Integrity is slated to be held in Rio de Janeiro in 2015.

The Future of Research Ethics

The governmental regulations and professional codes of ethics described above are only examples of the kinds of regulations that currently exist around the world – everywhere that research takes place. Given the early events that generated so much governmental concern about research ethics, it is hardly surprising that the treatment of human subjects became the object of so many regulations and oversight. Moreover, there have been an unfortunate number of recent breaches that reaffirm the need for vigilance. After all, the support and success of research – in all fields – ultimately depends on the public trust, and those early events, as well as others later on, challenge that foundation of trust.

The Singapore Statement and *The Montreal Statement* are solid indicators of what appears to be a trend away from the focus primarily on the treatment of human subjects and toward the wider range of issues implicit in research ethics. There are also indications of this trend in some of the governmental regulations (e.g., ORI) and disciplinary statements. Concerns over confidentiality, authorship, publication, conflicts of interest, and other issues do appear. However, at present, they still appear to be largely secondary to the need to protect human subjects from harm. Nevertheless, it does appear that this trend toward research ethics more broadly construed will continue and grow.

Ethical, Legal, and Social Implications Program at the National Human Genome Research Institute

Jean E McEwen, Joy T Boyer, Nicole C Lockhart, and David J Kaufman, National Human Genome Research Institute, Bethesda, MD, USA
Lawrence C Brody, National Human Genome Research Institute, Bethesda, MD, USA

Abstract

The Human Genome Project was a large coordinated effort designed to produce a highly detailed and dynamic picture of our genetic material. It was clear from the beginning of the Project that the results would raise a host of ethical, legal, and social issues. To address these questions, the National Human Genome Research Institute created the Ethical, Legal, and Social Implications (ELSI) Program, with the charge to fund basic and applied research on the ethical, legal, and social implications of genetic and genomic research for individuals, families, and communities. Nearly 25 years later, 'ELSI' has become a recognized term for research that deals with the social, legal, and ethical issues arising from advances in biomedical science.

Introduction

The Ethical, Legal, and Social Implications (ELSI) Program is a research program at the National Human Genome Research Institute (NHGRI), one of 27 institutes and centers of the US National Institutes of Health (NIH). In the mid-1980s there were a number of discussions about the need to have a detailed map of the human genome. These discussions were formalized in 1990 as the Human Genome Project (HGP) – a project funded jointly by the US Department of Energy and the NIH. The leaders of the HGP were aware that producing highly detailed information about human genomes might lead to discrimination based on an individual's genetic makeup. Also in the background were various discriminatory activities that had earlier carried out in the name of the eugenics movement. To ensure that the social implications of the science were addressed in step with the technical advances, it was decided that a portion of the funding for the HGP would support research on the ethical, legal, and social implications of the research.

Thus, the formal launch of the HGP in 1990 included the creation of the ELSI Program – a program designed to anticipate and address these issues. In the ensuing 24 years, 'ELSI' has become a recognized shorthand for this type of work even beyond human genome research. 'ELSI' is now often used as an adjective when describing other research programs and is also sometimes used as a noun when discussing specific programs, elements of infrastructure, and components of a research program.

The ELSI program received additional recognition as a defined entity via a 1993 US Congressional mandate that decreed that NHGRI shall allocate 5% of its annual research budget to support research into the ethical, legal, and social implications of genetics and genomics research (National Institutes of Health Revitalization Act of 1993). The rationale for the Program is to facilitate rigorous consideration of the implications of advances in genetics and genomics research at the same time that the underlying science is being conducted.

The ELSI Program is currently the only dedicated extramural bioethics research program at the NIH and is the largest funder in the world of research focused on ethical, legal, and social issues in genetics and genomics. The Program's budget has grown from $1.57 million USD in fiscal year 1990 to approximately $18 million USD in 2014. Since its inception, the Program has awarded more than $320 million USD in research support and has funded over 480 projects; collectively, these have resulted in thousands of scientific publications (McEwen et al., 2014).

The Program, which is administratively situated within NHGRI's Division of Genomics and Society (http://www.genome.gov/27550080), is shaped by ongoing advice from the National Advisory Council for Human Genome Research (NACHGR) (http://www.genome.gov/10000905). This body includes experts in genomic science and technology and genetic and genomic medicine as well as experts in emerging ELSI issues. The Program also obtains regular input from the Genomics and Society Working Group, a subgroup of the NACHGR established to make recommendations on short- and long-range planning and priority setting (http://www.genome.gov/27551917).

The present-day ELSI Program is fundamentally a research and training program. Although the studies that the Program supports often help to inform the development of policies related to genomic science and of education and community outreach activities, the direct support of policy development activities is beyond the Program's purview. In the past, the Program supported direct funding for education activities aimed at professionals or the public, but funding for education projects was discontinued in 2004 based on growing recognition that the Program was neither financially nor organizationally equipped to contribute meaningfully to the enhancement of 'genomic literacy' by producing educational materials. However, research projects designed to investigate the best practices to enhance and extend the knowledge of genomics still fall within the portfolio. In addition, the Program supports a variety of meetings, workshops, and policy conferences, some of which include educational components. The Program also supports many research training activities, and has been especially committed to

training aimed at increasing the diversity of the investigators who conduct ELSI research.

Overview of the ELSI Program Portfolio

The current research priorities of the ELSI Program fall into four broad categories: psychosocial and ethical issues in genomics research; psychosocial and ethical issues in genomic medicine; legal and public policy issues; and broader societal issues (Green et al., 2011). In 2014, roughly 40% of the current budget funded studies of genomics research issues, 33% to studies of issues in genomic medicine, 11% to legal and policy studies, and 16% to studies of broader societal issues (McEwen et al., 2014). These percentages are not fixed and the Program has been designed to evolve as genomic science and genomic medicine advance.

The Program's research portfolio incorporates work by investigators from a broad range of disciplines, including (among others) genetics and genomics, clinical medicine, bioethics, the social sciences (e.g., psychology, sociology, anthropology, political science, and communication science), history, philosophy, literature, law, economics, health services, and public policy. Many of the individual grants are themselves highly multidisciplinary. Funded projects employ a wide range of empirical (both quantitative and qualitative) and nonempirical methodologies. These range from experimental and quasi-experimental trials, surveys, focus groups, and structured and semistructured interviews, to ethnographic, legal, philosophical, archival, and oral history research. The ELSI Program aims to maintain a balance of grants that utilize empirical and nonempirical methods, and nearly half the grants in the Program's portfolio employ multiple methods.

Projects funded by the Program may be undertaken either as stand-alone efforts or embedded in much larger multidisciplinary projects with multiple objectives, ranging from technology improvement to clinical trials. In the latter types of projects, the ELSI implications of the science can be investigated in parallel and in real time along with the primary objectives of the underlying study.

Funding Mechanisms and Mechanics

The ELSI Program solicits both investigator-initiated and program-initiated research. Investigator-initiated research applications are solicited through general Program Announcements that contain broad statements of ongoing areas of programmatic interest.

Program-initiated studies – studies of particular high-priority topics that are periodically identified as requiring immediate or more focused attention – are solicited through targeted Requests for Applications or Requests for Proposals. Past examples of these Program-initiated projects include calls for research into such topics as the ethical and legal implications of cancer genetics predisposition testing, the societal implications of genetic variation research, and the issues raised by the return of genomic research and test results and incidental findings.

A currently active example of a Program-initiated project is the Centers of Excellence in ELSI Research (CEER) Program (http://www.genome.gov/1504773). The purpose of the CEER Program is to support the creation and maintenance of the infrastructure necessary to foster highly transdisciplinary academic research, facilitate the translation of such research into health, research, and public policies and practices, and train the next generation of investigators in the field. In its current form, this program consumes roughly one-third of the ELSI budget.

Although the ratio of investigator-initiated to Program-initiated research fluctuates from year to year, historically, most of the research funded by the Program has been investigator-initiated, reflecting the Program's desire to promote the intellectual independence of its supported investigators. All grants submitted to the Program undergo a peer review process that utilizes the standard review criteria applied to all NIH applications.

Program Priorities – Breadth versus Depth

In setting program priorities, the ELSI Program strives to maintain a balance between breadth and depth in its research portfolio, while taking into account the broad range of stakeholder interests involved. The need for careful priority-setting has been especially pronounced since 2010 because of the shift that is occurring in the field of genomics from an emphasis on basic research (research aimed at understanding the structure and biology of genomes and the biology of disease) toward an emphasis on research with identified human participants and immediate clinical applications (Green et al., 2011). The latter type of research raises an expanded array of ethical issues, which the ELSI Program is increasingly called upon to address.

Pressures on the Program to spread its limited research dollars across a wider range of topic areas began to occur just as the budget for NIH (and thus NHGRI) became more restricted, which has heightened priority-setting challenges for the Program. For this reason, the Program must continually reassess the extent to which its resources should be allocated to the support of certain categories of research which, in a less-constrained budgetary climate, would likely have been supported, such as studies that are 'disease-specific' as distinct from those aimed at the development of models with potentially broader applicability. Similar questions have begun to arise about the extent to which the Program's resources should be devoted to research on issues arising from uses of genomic information in nonmedical contexts (i.e., studies addressing topics such as potential uses of genomic data in insurance, employment, education, criminal justice, family law, and the military) or research that has a non-US or explicitly international focus.

Integration of ELSI Research with Genomics Research and Policy Activities

Interactions between the ELSI and genomics research communities and between the ELSI research and policy activities have always been a feature of the ELSI Program, but such

interactions have grown more frequent since the early 2000s. On the research side, as earlier noted, the CEER Program has as an explicit goal the building of transdisciplinary research teams that include both ELSI and genomics investigators. Several large community resource projects coordinated by NHGRI also provide opportunities for interactions between genomics investigators and those with expertise in the ethical, legal, and social issues those projects raise. Opportunities for collaborations have come about through 'stand-alone' RFAs issued to support ELSI research conducted in parallel with corresponding genomics initiatives, through the establishment of Working Groups for large initiatives to provide guidance on particular issues, and more recently, through the direct 'embedding' of ELSI research within genomics research protocols.

On the policy front, many investigators supported by the ELSI Program participate actively with various policy bodies. At the national level, these include the Secretary's Advisory Committee on Genetics, Health and Society, the Secretary's Advisory Committee on Human Research Protections, the Discretionary Advisory Committee on Heritable Disorders in Newborns and Children, the Presidential Commission for the Study of Bioethical Issues, and the policy and bioethics committees of most of the major professional societies related to genetics.

Increasing integration between the ELSI research enterprise and the genomics research and genomics policy enterprises carries with it a number of significant benefits. For example, in the research realm, directly embedding ELSI research into active, ongoing genomics research provides a 'natural laboratory' for conducting such studies, sometimes generating more reliable and more practically relevant findings than those arising from hypothetical studies. Closer collaborations between ELSI investigators and genomics researchers have also helped ELSI investigators become more conversant with genomic science and genomic investigators become more conversant with some of the methods used in other disciplines (including normative methods) – thus enhancing mutual respect and understanding. On the policy side, increasing integration between ELSI investigators and those charged with the development of policy has tended to increase the policy relevance of the research. This increases the amount and quality of evidence on which to base policies related to genomics whether in the sphere of research, clinical medicine, or society more broadly, and enhances the likelihood that these policies will be solidly evidence based.

On the other hand, increased integration between the ELSI research enterprise and the genomics research and policy enterprises has occasionally come with a downside, as some risk exists that ELSI investigators will come to be seen as mere 'facilitators' of genetic and genomic research, or as tools of others' particular policy agendas. Indeed, concerns have occasionally been expressed that encouraging too close an integration between the enterprises runs the risk of a subtle erosion in the legitimacy of ELSI investigators' standing as independent and autonomous academic investigators. In fact, however, a large portion of the ELSI budget is spent on investigator-initiated grants, helping to ensure the continuation of a healthy independent ELSI research agenda.

The challenges involved in promoting enhanced integration among ELSI research, genomics research, and policy development activities, while simultaneously maintaining the objectivity, intellectual independence, and integrity of ELSI investigators, have been well recognized since the inception of the ELSI Program. To a large extent, these challenges arise from the simple fact that the Program, while charged with supporting critical investigations into the ethical, legal, and social implications of genomics research, is organizationally, and indeed physically, situated within the very agency that supports the underlying science.

Impact of the ELSI Program

Assessing the impact of the ELSI Program is challenging for several reasons. First, many of the studies funded by the ELSI Program involve basic research (e.g., the clarification of terminology and concepts or the analysis of moral frameworks, values, or cultural constructs) – a kind of research that does not always have a direct impact on policy or practice but which does help to provide a foundation on which more applied studies can be built. Second, not all of the issues addressed by ELSI research have direct relevance to specific policy enactments (at least under a narrow definition of 'policy'). Third, the trajectory between the dissemination of ELSI research findings and the establishment of research, clinical, or broader societal policies related to genomics tends to be nonlinear. Finally, as ELSI research is often aimed at anticipating where the science and technology will be in the future, the program may fund research into the implications of genomic methods, techniques, and applications that fail to materialize.

Indeed, the impact of ELSI research has often come less from the direct 'translation' of published study findings into a formal embodiment of policy than from ELSI investigators – operating independently as scholars, beyond the immediate scope of their NIH-funded activities – serving directly on particular commissions or other policymaking bodies or providing expert testimony or other forms of expert analysis to those groups (Burke et al., 2014). The most consequential impact of ELSI research may, in fact, come about in even more subtle ways, such as through the contributions the studies have made to incremental changes in the cultural milieu in which genomics research is conducted, genomic medicine is implemented, and genomic information is incorporated into decision-making in various areas of society more broadly.

In the realm of genomics research, for example, ELSI research on issues related to privacy and the potential identifiability of genomic data (Kaufman et al., 2009; McGuire, 2008) has led to changes in the way investigators draft, and the way institutional review boards review, consent forms and consent processes for genomic studies. Such research has also influenced the ongoing development of NIH-wide policies on genomic data sharing and proposed revisions to US federal regulations regarding the conduct of research.

Research on the ethical issues relating to the use of stored genetic samples (Clayton et al., 1995; Fullerton et al., 2010) has influenced the development of policies and practices for biobanks and biorepositories and the development of innovative governance mechanisms for these entities. Research on community engagement, community consultation, and group interests in genetic variation research, and on the ethical and

social considerations involved in the labeling of populations (Foster et al., 1999; Sankar and Cho, 2002) has led to the development of novel protocols to engage and consult with the socially defined communities approached for participation in several major international research projects and to the adoption of more precise and ethically sensitive nomenclature for the populations studied. Ongoing studies of novel approaches to community-based participatory research (James et al., 2012; Kelley et al., 2012) are serving as a model for genomics research conducted with diverse populations and for emerging 'Citizen Science' initiatives.

The impact of research supported by the ELSI Program can also be observed in the evolution of policies related to the use of genomic information in the clinic. A long line of studies of the ethical and social issues in various settings, including population-based screening (Anderson et al., 2005; Clayton et al., 1996), carrier testing (Callanan et al., 1999; Faden et al., 1994), prenatal testing (Botkin, 1998; Robertson, 2003), newborn screening (Botkin, 2005; Waisbren et al., 2003), and predictive testing of both children and adults for both early and late-onset conditions (Burke et al., 1997a,b; Tercyak et al., 2007), and (most recently) whole exome and whole genome sequencing have contributed to the development of a number of Points to Consider documents, recommendations, guideline statements issued by professional organizations, and occasionally to enactments by other policymaking bodies. Studies of the attitudes of research participants and patients about the return of results and incidental findings (Kaufman et al., 2009) and studies of the experiences of customers of direct-to-consumer genetic test marketing companies with the receipt of genetic test results (Bloss et al., 2011; Bollinger et al., 2013) are contributing to researchers' and clinicians' awareness of what people want and expect, how they perceive risk, and how complex genomic information can be communicated in ways that are easier for people to comprehend.

In the broader societal domain, normative and legal analyses relating to genetic privacy and the risk of genetic discrimination supported by the Program, especially in its earliest years (Hudson et al., 1995; Rothenberg et al., 1997), helped create momentum that led, sequentially, to the issuance by the Equal Employment Opportunity Commission of guidance suggesting that discrimination based on genetic predisposition is prohibited by the Americans with Disabilities Act, to an Executive Order protecting federal employees from genetic discrimination in the workplace, to the inclusion in the Health Insurance Portability and Accountability Act of a provision prohibiting group health insurers from excluding individuals from group coverage based on genetic predisposition, and eventually, to passage of the US Genetic Information Nondiscrimination Act, which prohibits genetic discrimination in most areas of health insurance and employment. Research on ethical, legal, and social issues related to uses of DNA in the courtroom (Noble and Moulton, 2006; Scherr, 2013) has helped to sensitize judges, lawyers, civil liberties advocates, and members of the law enforcement community to the issues involved in the collection and potential use of DNA samples from people brought into the criminal justice system.

Research on the ethical and social implications of emerging behavioral genetics findings (Parens et al., 2006; Phelan, 2005) has led gradually to greater media awareness of the need for nuanced discussions of this issue and has heightened awareness among judges, and others involved in the legal system of the complexities involved in using behavioral genetics evidence in courtrooms and other societal structures. In addition, legal and economic analyses regarding the effects of gene patents and other types of intellectual property protection on genomics research and on access to genetic and genomic tests (Henry et al., 2002; Rai and Sampat, 2012) have provided data that have helped to inform policy development in this area.

Conclusion

In the first 24 years of the ELSI Program, the research it funded often focused on the theoretical possibilities of genomic science. Today, the sequence of the human genome has been completed and genomic technologies are improving at a rapid pace. This setting makes it even more critical to carefully examine and explore the implications of these scientific advances. Ignoring the social, legal, and ethical implications of this work could lead to a loss of return on scientific investment if the products of these advances are not understood or accepted. Supporting a research agenda that engages the public and various professional communities that are likely to be impacted by the work can help to ensure that the scientific and technical advances will not be lost in translation.

This article is a revision of the previous edition article by R.J. Levine, volume 7, pp. 4770–4774, © 2001, Elsevier Ltd.

Abstract

This article provides an overview of the history, development and regulations, composition and performance, hopes and hindrances related to the committees in the United States charged with the protection of human subjects in research studies. Often referred to as Ethical Review Committees, Ethical Review Boards, or the Institutional Review Board, the roles of these risk-management committees are explored, with an emphasis on contemporary issues and concerns as well as the power they have in requesting modifications to scientific protocol and in making the ultimate decisions for approval.

Lessons from the Past and Development of Regulation

Most researchers are bound to a professional code of ethics and operate within ethical guidelines. Simply defined, in clinical practice ethics are rules to help professionals distinguish between what is right and wrong. When ethical practice becomes research, however, the focus switches slightly to focusing on minimizing the risks of those who participate while conducting scientifically valid research. The fluid nature of ethical conduct, by definition, is a continuous process (Fujii, 2012). Ethical practice, with its inherent decision-making principles, needs constant updating and reexamination to ensure that environmental and technological advancements are included. Therefore, there is rarely a simple response or check-box answer that will ensure that all human subjects are protected. Ethical decision-making is a complex task, and it can also be somewhat elusive.

The rights and welfare of human subjects have not always been considered; at times individuals have been used with no concern for their autonomy or safety. Many professionals are familiar with the Nazi medical experiments of the 1930s and 1940s where brutal mutilative surgery was performed in the name of science. Following World War II (1946–49), tribunals were held in the Palace of Justice in Nuremberg, Germany to review the travesties that were reported. These tribunals recommended a set of research ethics termed 'The Nuremberg Code.' The Nuremberg Code of 1947 outlined 10 principles related to ethical conduct. This Code was the first to emphasize the importance of protecting research participants by means of informed consent with the absence of coercion and properly designed experimentation that minimizes risk and maximizes benefits. In the 1960s, the issue of human participant rights was further highlighted by the Declaration of Helsinki formulated by the World Medical Association in Helsinki, Finland. This document went beyond the Nuremberg Code by focusing primarily on ethical principles related directly to medical research and is often considered an overarching precursor to the guidelines practiced today in the United States. The Declaration of Helsinki provided the basis for an international standard that recognized the importance of biomedical research involving human subjects and that mandated that each research protocol be reviewed by a specially appointed Ethical Review Committee (ERC) (World Medical Association, 2000: Article 13).

The horrors uncovered in the Nuremberg tribunals, were brought closer to home when the American people were alerted to the Tuskegee Syphilis Study. This shocking violation of human dignity still ripples through the hearts and minds of a previously trusting public. This study first began in 1932 when the U.S. Public Health Service (USPHS) started a 40-year clinical study of the effects of untreated syphilis on black males. Over 600 low-income study subjects were promised free health care by the government, along with meals and burial rights. When a cure for the disease was discovered in 1940s (penicillin), the participants were not told and some were actually prevented from receiving treatment. In May 1997, President Clinton issued a formal apology to the survivors of the Tuskegee study and their families. In addition, a second study, from 1946 to 1948, also supported by the USPHS, in collaboration with Guatemalan health authorities, deliberately infected prisoners with sexually transmitted diseases such as syphilis. The Guatemalan prisoners were provided treatment, however, this was all done without their informed consent. After the discovery and exposure of the Guatemala study in 2010, the President of the United States issued an apology to the Guatemalan people in general because those individuals who were actually harmed could not be found (NIH, Fact Sheet, n.d.).

Given the misuse of research subjects in the past it became clear that a set of guidelines was essential if research ethics were to be put into practice. The National Research Act was signed into law by the U.S. Congress on 12 July 1974. This Act authorized the creation of the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research. This commission identified basic ethical principles and in 1978 released a document entitled *The Belmont Report*. *The Belmont Report* identified three major principles: (1) respect for persons; (2) beneficence and 'do no harm'; and (3) justice (The Belmont Report, 1979).

For researchers in the United States, this effort culminated with what is usually referred to as the 'Common Rule.' This regulation is advanced by the Office of Human Research Protections (OHRP) which is responsible for safeguarding the rights, welfare, and well-being of research subjects in the

conduct of federal research. To ensure compliance OHRP, supported by the U.S. Department of Health and Human Services (HHS), oversees biomedical and behavioral science research institutions ensuring compliance with HHS regulations as described in Title 45, Part 46, Code of Federal Regulations (45 CFR 46). The Common Rule defines research as a systematic investigation designed to develop or contribute to generalizable knowledge. This includes research, testing, and evaluation on human subjects. The Common Rule further defines human subjects as any living individual where data about the individuals are obtained either through intervention or interaction or includes private, identifiable data [45 CFR 46.102(f)]. "Thus, according to the Common Rule, as currently written, research involving material from deceased individuals (e.g., autopsy material) or the use of specimens that are completely anonymous (i.e., a link to subject identity does not exist), would not be subject to the Common Rule, although state and local regulations and policies may apply" (Bledsoe and Grizzle, 2013: p. 324).

When looking specifically at nonbiomedical research, effective and efficient application of the Common Rule requires:

1. an Institutional Review Board (IRB) that has sufficient expertise in social and behavioral research;
2. an IRB that understands and utilizes the flexibility in the Common Rule; and
3. investigators who understand the potential for social and psychological risk in their research.

The Health Insurance Portability and Accountability Act

The importance of those in clinical practice as well as researchers gaining access to a participant's health-related information is coupled with a need to protect the privacy and ensure the consent of all research participants. This need to control a patient's identifiable information provided the impetus for the creation of the Health Insurance Portability and Accountability Act (HIPAA) Privacy Rule in 1996, (Health Information Privacy, 2014). Based on previous incidents of researcher misconduct and the public fear that private information would be used or misused without proper informed consent, guidelines were put in place to control access to both health and mental health-related information. Designed to protect the consumer, this Act identified and clearly defined what constitutes a participant's Protected Health Information (PHI). At times PHI may need to be released and this Privacy Rule allows for the release of such disclosures for treatment or other purposes with the expectation that certain protections be put into place. In practice today, HIPAA has carried over into research activity and when PHI is collected, a detailed plan for outlining what will be collected and analyzed, how it will be retrieved, who will have access, how it will be securely stored, and when it will be destroyed will be a necessary part of the participant's awareness requiring consent. The researcher must explain and justify his or her reasoning when requesting a waiver of participant, such as when the study is minimal risk, the waiver will not adversely affect the rights and welfare of the subjects, and the research would not be practicable if consent were required.

Ethical Oversight in the United States: The Formulation of the IRB

The Nuremberg Code and the original Declaration of Helsinki were helpful in formulating the basis for ethical conduct of research, but made no direct statement as to the importance of formulating an ethical review panel. Historically, the expectation for ethical research was placed on the investigator with little, if any, system of checks and balances. In the United States, the first federal document requiring committee review was issued on 17 November 1953. This document and its guidelines applied only to research conducted at the newly opened Clinical Center at the National Institutes of Health (NIH) (Lipsett et al., 1979). The first mention of committee review from an international perspective was in Tokyo with a revision of the Declaration of Helsinki (World Medical Association, 1975).

Learning from the mistakes of the past, all research-savvy institutions in the United States that conduct research involving human subjects have access to an *IRB*. In some cases, the IRB may be viewed as an independent ethics committee or referred to as an *Ethical Review Board (ERB) or Research Ethics Committees (REC)*. In countries other than the United States, the term REC is most common, whereas in the United States the most common term is IRB. In Canada, the term Research Ethics Board (REB) has been used with similar authority to approve or disapprove research proposals (Medical Research Council of Canada, 1987). In the United States, one significant pronouncement that can be seen as a forerunner for today's IRB came on 8 February 1966, from the Surgeon General of the USPHS. The Surgeon General issued the first federal policy statement requiring research institutions to establish the committees which subsequently became known as RECs and ultimately IRBs (Curran, 1970). Focusing on USPHS grant funded research, the grantee's institution, in cooperation with the investigator and his or her institutional associates, were expected to be responsible for the oversight of projects involving human subjects.

The conception of IRB oversight rests in three important concepts. (1) These boards serve as the official designated guardians of the rights and welfare of the participants that serve in research studies under their purview. As central units, it is clear that these boards have the responsibility and are empowered to review and monitor the research activities and ultimately have the ability to approve or deny the research protocol being submitted. (2) As the scope of research extends far beyond traditional expectations, an updated systematic review is needed that takes into account participant awareness, consent, and safety, but also balances federal regulation with ethical expectations in research conduct. Lastly (3), the IRB is expected to ensure that the research is conducted in a transparent and scientifically feasible way while evaluating whether it is ethically sound, thereby protecting the rights of all human subjects involved.

Defining vulnerable subjects can be problematic. In its simplest definition 'vulnerable' includes individuals who, in

health care or research are at the greatest risk of being harmed or have greater susceptibility to being harmed (Hurst, 2008). Protecting human subjects who are most vulnerable rests at the heart of ethical conduct. This type of protection requires additional attention to any structural or systematic bias and introduces a *subject surrogate* that serves as an expert in the area. For example, related to the unique and vulnerable role of prisoners, DHHS regulations require that an REC/IRB member regularly review research that involves this vulnerable category of subjects. This board representative is specifically assigned to review any research related to this population. This reviewer scrutinizes these protocols to ensure that the rights of vulnerable populations have been addressed. Other vulnerable groups include children, pregnant women, and those that are considered mentally incompetent.

Ensuring Ethical Conduct: The CFR

Today, in the United States it is clear to all that human participant research must be conducted in compliance with federal regulations. The Division of Education and Development provides guidance to individuals and institutions conducting HHS-supported human subjects' research. The Division of Policy and Assurances administers the *Federal-wide Assurance* (FWA) of compliance and registration of IRBs. When an IRB is formed a FWA is completed with the HHS, and, therefore, must meet all the HHS regulations. All risk-management reviews need to be conducted with subsequent approval required by law. All research-related activities carried out under the institution's auspices that are supported by federal funds are subject to regulation by the Food and Drug Administration. Often referred to as 'checking the box,' in addition to the legal requirements for federally funded research, many institutions also voluntarily extend the requirement for IRB review to all research involving human subjects.

Once an IRB is established (as published in the Federal Register on 15 January 2009), it must be registered. IRB registration falls under (74 FR 2358), 21 CFR Part 56, IRBs, and amended with regard to IRB registration (21 CFR 56.106). HHS monitors and updates this Internet-based registration system for federally funded research. In addition, an assurance document is generated between the institution and HHS that the institution will comply with federal guidelines for the protection of human subjects and adhere to regulations [45 CFR part 46] with the assurance mechanism described in 45 CFR 46.103.

Understanding how membership of this committee is established is an important first step in ensuring that it can complete its important tasks. IRB membership must include at least five appointed members. It is expected that every effort should be made to create a culturally and professionally diverse committee taking into account race, gender, and cultural backgrounds, as well as affiliation. There is no regulation that says that members cannot be compensated. In addition, at least one of the members should be from the scientist area and one must be a nonscientist. There should also be at least one appointed member that has no connection with the institution apart from committee membership, although absence of this member can still constitute a quorum for decision-making. There are many professionals that can serve on the committee and depending on the types of research reviewed, composition can vary. It is important to note that IRB members do not need to cover every discipline or research area; when needed the IRB can and should obtain information and guidance from outside consultants as they make their research determinations.

Establishment of the IRB: Basics for Structure and Functioning

For many institutions the IRB is located in the facility and remains an integral part of its research activities. For others, the activities of the IRB may be outside of the institution, often referred to as *central review boards*. Regardless, the oversight of the studies conducted by either affiliated or nonaffiliated researchers is their purview.

The purpose of the IRB, ERB, or the ERC is clear in that it is designed to protect the rights of human subjects that participate in research-related activities. The goal of these boards is to ensure that research involving human subjects is designed to conform to relevant ethical and legal standards while safeguarding the rights and welfare of individual research subjects, ensuring informed consent, and minimizing risks while maximizing any anticipated benefits. Originally, these committees were created to provide oversight for biomedical research; however, today their domain has been extended to also cover research in the social and behavioral sciences. To complete this task, these boards are expected to perform a type of risk–benefit analysis that ensures all research conducted with its oversight will be performed ethically and legally within expected compliance standards. When research is conducted in the United States, every precaution needs to be taken to ensure that regulations designed to address the needs of participants are followed.

Membership of the IRB should contain an interdisciplinary group of professionals made up of diverse professionals such as doctors, nurses, lawyers, scientists (including those skilled in the biomedical area and behavioral scientists such as psychologists and social workers) as well as clergy that bring professional expertise to the review process. These professionals under the leadership of a Chair utilize a jury model that incorporates a risk-management strategy capable of confirming scientific merit as well as ethical conduct always reflecting common sense principles of reasonable expectations.

Avoiding Conflicts of Interest

Although incredible gains in knowledge and human understanding and betterment may result from research findings, how they were obtained and what was done to human subjects to achieve them remains a core issue. Secondary gain and whether the researcher may personally benefit from the research study requires careful consideration.

To help avoid the potential for 'conflict of interest,' all studies, especially those that are deemed to be more than minimal risk require the diverse membership of a board of

scientists and nonscientists that oversee the process. In addition, it is expected that at each meeting – prior to starting protocol reviews and the risk-management discussions – that members should identify any conflicts of interest. Once identified, the member should absent him or herself from discussions and abstain from voting on any relevant protocols. The Chair of the IRB is responsible for ensuring this is done at each meeting and if the Chair has a conflict, a substitute Chair for the proceedings should be appointed.

Mission Creep and Criticisms of the IRB

IRB leadership and participation is not for the squeamish and it should come as no surprise that this type of work rests heavily on all involved. Historically, complaints about the IRB overstepping its bounds are nothing new. Concerns related to the development of ethical guidelines, codes, or sets of procedures concerning the 'conduct of research' prevailed in the medical research community (Curran, 1970). Furthermore, in the 1970s biomedical scientists and social behavioral scientists alike remained harshly critical of the role of the IRB and its risk-assessment practices (Levine, 1988). The social behavioral researchers felt strongly they were far less likely to harm human subjects, when compared to a biomedical scientist, and they questioned whether they should be held to the same rules. The behavioral scientists believed that because they did not complete medical procedures or gather tissue from participants and only spoke with them that equivalent regulations were an unconstitutional constraint on their freedom of speech (Levine, 1988).

Similar to earlier objections, concerns are still voiced regarding many areas of research oversight, including community-based participatory research. These complaints from investigators related to oversight of their research activities are not uncommon and at times the assumption is they fall upon deaf ears (Wolf, 2010). At the root of this controversy is whether the REB/REC/IRB really has the skill and expertise to approve or disapprove the scientific design of research protocols (Levine, 1988). After all, who knows better the scientific design than those who created it? This requires that REB/REC/IRBs identify what constitutes a strong and comprehensive design with the intention of providing oversight and awareness of what also meets ethical requirements designed to protect human subjects. Moreover, they argue, the IRBs obligation to determine that risks to subjects are reasonable in relation to anticipated benefits necessarily relies on a prior determination that the scientific design is adequate, for if it is not, there will be no benefits and any risk must be considered unreasonable.

Just by virtue of the power vested in their review, guidance, monitoring, and approval power it is clear why some researchers are wary of the IRB and the potential for *mission creep*. Mission creep defined simply is when the power vested in the IRB extends its bounds and goes beyond what is covered in the federal regulations. This type of extension, in its worst case scenario, is conflict driven and not directly related to the protection of human subjects. It therefore may be directly related to institutional legal concerns and protecting the university or in pushing the self-interest of board members or others in institutional leadership positions. It is clear that there is often a fine line between ensuring a subject's rights, institutional liability, and balancing what might be termed overarching yet limited federal guidelines – all of which rarely provide direct guidance for every situation. For those serving on the IRB, as well as the scientific investigators, should not this always be a test for weight and balances? Should federal law be adhered to the letter even when situations are not fully addressed by the general guidelines provided? Yet, who monitors the IRB and how is their work overseen?

Although no comprehensive answer is provided, steps along the corrective path include: Continuing education for board, investigators, and the community; and, regulation of IRBs by an independent body such as Association for the Accreditation of Human Research Protection Programs. This independent accreditation body can work to protect the rights of human subjects and foster clear guidelines for institutions, self-assessment, peer-review of all policy and procedures, and education.

When continuation for RECs and IRBs are required, this type of training needs to be updated regularly and reflective of changing technologies in research methods as well as public policy initiatives (Wolf, 2010). Most IRBs already have such policies and procedures in place but clear budgeting and allowances for such updating are vital. This includes budgeting for attendance at conferences where the sharing of the latest information and exchange of ideas with those familiar with IRB requirements and activities is essential. For those on the board, required training should take place at each meeting as well as through a systematized fashion on a cycle of renewal. In addition, there are certificates and additional training that can make board members aware of how to best apply the federal guidelines and any subsequent changes that occur. In turn, the scientific investigators should also receive updated training. To have investigators aware of the latest rules makes it a win–win for all in terms of review, modifications, and subsequent approvals. Lastly, the human subject, now generally referred to as the participant in the study, clearly can benefit from learning more about informed consent and what to or not to expect in any research study, not just the one he or she is invited to participate. An educated public helps to avoid confusion and can empower participants to ask the questions they have not thought to ask before. This requires that continuing education remain rich with updated policies and procedures essential for the success of any IRB.

Conclusions: Pulling It All Together

After the lessons learned in the past, some researchers continue to question the IRBs role in the protection of human subjects in clinical and behavioral science research. With the gains made through regulation, some professionals continue to wonder whether there are still gaps that occur in study conception and implementation (Slade et al., 2012).

This is complicated by federal regulations that are written in vague language in contrast to the clearer direction provided for protecting subjects' rights. A board composed primarily of professionals may be more scientifically curious than those with less training in the lay public. Such a board could be more

likely to vote in favor of proposals that may be considered of higher risk based on the potential for the gain of scientific knowledge. Lastly, as is true in any group process, a gathering of the minds can lead to *group think* where members of the group are influenced by a charismatic leader.

Gaining approval of the IRB has never been more persuasive when increasingly academic settings require faculty to conduct research and publish the results to advance the profession. Similar, to publish these research findings and contribute to the literature, academic, and rigorous journals will not publish the information gathered if it has not had prior IRB review and approval. This makes escape from IRB oversight almost impossible if one wishes to contribute scientific information to the literature. Pressure on IRBs to meet unrealistic deadlines and expectations that go beyond federal regulations can lead to 'mission creep,' a concept that only slows the process and discourages a professional collegial and supportive relationship between the researcher and the board (Saleem and Khalid, 2011).

Furthermore, are we really drawing a line in the sand when we try to separate out research from clinical practice? Can one really be distinct from the other? If so, then applying different rules makes sense. If not, trying to apply different rules and oversight of certain aspects of practice by calling it research may mislabel and subsequently misrepresent clinical inquiry (Anderson, 2010).

When the potential for mission creep is mixed with a blurred definition of what is clinical practice and what constitutes research, the lines between the two heighten the existence of the other. The more blurred the definitions, the greater the mission creep and the more complicated decisions become. Contemporary considerations and global connections make the situation even more complicated. When scientific investigations that are funded by U.S. enterprises such as pharmaceutical companies extend into developing countries, the need for control with limited red tape becomes even more evident (Saleem and Khalid, 2011). How does one truly stop the seductive benefits of secondary gain filled with researcher bias? Also, with changing technology problems continue to evolve related to ensuring consent to storing data in the cloud. As scientific and technological advances continue, the usual conflicts related to the varied professional interpretations of what constitutes ethical conduct designed to protect human subjects will make disagreements and differences in opinion unavoidable. Research regulations and the work of the IRB committee remains at the heart of risk-management review. These activities, however, will continue to fall short if this responsibility is not assumed deep in the core activities of the principal investigator and his or her research colleagues. In closing, this leads to one primary assumption, IRBs can help provide risk-management assessment, but the true ethical imperative to safeguard the participant must always rest with the individual investigator and his or her colleagues.

Few would disagree that the use of human subjects in research has led to significant scientific and medical advancements and equally few would question the need to protect research subjects from the potential for abuse (Bledsoe and Grizzle, 2013). In fact the rights and welfare of human subjects should always be considered first because it is the only way to ensure participant autonomy and safety.

Ethical Questions in Social and Behavioral Sciences, History of

Andrea Ploder, University of Graz, Graz, Austria

Abstract

A systematical discussion of Ethical Questions in the Social and Behavioral Sciences (SBS) started to unfold in the United States during the 1940s and 1950s and came to a provisional climax in the late 1960s and early 1970s. During this time, several ethical codes were released and collected volumes on the matter published. The debate brought about considerable shifts in perspective in the professional communities. Throughout the 1970s and 1980s, it slowly flashed over from the United States to Canada and Europe. Today, ethical codes and committees have become scientific 'normality' in most of the SBS.

Ethical Questions in the Social and Behavioral Sciences (SBS) are manifold. They touch on a broad variety of topics and are discussed with reference to a wide range of principles – from respect for human dignity and informed consent to the misuse of expertise and the upholding of scientific standards. Today, ethical codes and committees have become scientific 'normality' in most of the SBS. They appear in supervising agreements, dissertations, research funding forms, etc. From a historical perspective, the institutionalization of ethical concerns is a rather recent phenomenon. Ethical codes have developed with different rapidity, shape, and binding force among the disciplines and national communities.

This entry addresses the history of research ethics in the SBS from different angles. It starts with a sketch of early developments in other disciplines and professional contexts – the 'prehistory' of research ethics in the SBS and continues with early debates and institutionalization processes in psychology, sociology, and anthropology. The next section discusses some prominent cases in order to show the dynamics of the development from within the debates that shaped them. The last section addresses further factors that need to be taken into account in order to understand the history of research ethics in its complexity.

Prehistory

Within the SBS, ethical questions were no big topic before 1940. There was hardly any debate in leading journals, and academic associations did not release official codes of conduct. Some debates from the late nineteenth and early twentieth centuries, which would nowadays be framed as ethical, were framed as epistemological problems at that time.

Outside the SBS, the debate on research ethics has much a longer tradition. The most prominent arena was the field of medicine and medical research, where the first known codification dates back to the fifth century BC – the Hippocratic Oath. In 1830, John William Wilcock published his *Laws Relating to the Medical Profession* and in 1912, the *American Medical Association* released *The Principles of Medical Ethics* (for further detais see Lock, 1995, p. 515). The *Nuremberg Code*, released in 1947 subsequent to one of the Nuremberg trials, stated ethical principles for humane experimentation and medical research. It focused on informed consent, non-coercion, and the benefit of the research participants. Moreover, a lot of professional codes of ethics were released during the 1940s, most of them by nonacademic professional organizations in the United States (see Hobbs, 1948).

Early Debates and Institutionalization

Debates on ethical issues came up at different times and with different intensities throughout the various national SBS communities and disciplines. Starting prominently in the United States, they spread to other countries and international associations. **Table 1** compares professional codes of ethics in psychology, sociology, and anthropology in different national and international contexts by the year of their first release. It shows remarkable asynchronicity between the United States, Australia, and Europe, and also between the disciplines.

In economics, debates on ethical questions came up during the 1970s as well, one very early proponent being Kenneth J. Arrow (1973). He argued that – under certain circumstances – "ethical codes can contribute to economic efficiency" (p. 318). Still, Arrow and other economists concerned with ethical questions were and still are focused on *business* ethics – not on ethical standards for economic *research*. In recent years however, national and international economic associations started to formulate disclosure policies for their journals. In July 2012, the American Economic Association released a disclosure policy for all of its journals. The same goes for the Royal Economic Society (Great Britain) and its Economic Journal (2012), as well as the Canadian Economic Association with its journal CJE (2014). Neither of these associations have released a code of ethics for its members so far. According to its current office, the European Economic Association (EEA) set up an Ethics Committee in August 2013 which reported back to the EEA Council in August 2014. The Royal Economic Society – to give an example – requires a disclosure of "any financial or other interests or connections that might raise any question of bias in the work reported or the conclusions" for every submission to the *Economic Journal* (RES, 2012).

As becomes clear from the table above, early debates on ethical guidelines for SBS researchers were focussed on the psychological, sociological, and anthropological

Table 1 Codes of Ethics in the Social and Behavioral Sciences: years of first release

	Psychology	*Sociology*	*Anthropology*
International Associations	1976 Resolution Concerning Professional Ethics in Psychology (The International Union of Psychological Science)	2001 Code of Ethics (International Sociological Association)	——— (International Union of Anthropological and Ethnological Sciences)
European Associations	1995 Carta Ethica or Charter of Professional Ethics for Psychologists (European Federation of Psychologists' Associations)	——— (European Sociological Association (ESA)). (According to its current office, the ESA plans to release a Code of Ethics by 2014.)	——— (European Association of Social Anthropologists)
United States of America	1953 Ethical Standards of Psychologists: A summary of ethical principles (American Psychological Association) 1973 Ethical Principles and Guidelines in the Conduct of Research With Human Participants (American Psychological Association)	1971 Code of Ethics (American Sociological Association)	1971 Code of Ethics (American Anthropological Association (AAA)) 1973 Statements on Ethics. Principles of Professional Responsibility (AAA)
Canada	1986 Code of Ethics for Psychologists (Canadian Psychological Association (CPA).) (According to its current office, the CPA used the APA Code from the 1950s until the release of their own Code of Ethics. The first steps toward a CPA Code were taken around 1970.)	1994 Statement of Professional Ethics (Canadian Sociological Association)	1994 Statement of Professional Ethics (Canadian Sociology & Anthropology Association)
	1998 Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans (Canadian Institute for Health Research, Natural Science and Engineering Research Council, Social Science and Humanities Research Council)		
Australia	1949 Code of Professional Conduct (since 1997: Code of Ethics) (Australian Psychological Society)	1998 Ethical Guidelines (The Australian Sociological Association (TASA).) (According to the current TASA office, the need for a code of ethics was first raised in 1971. A code was drafted in the 1970s but not adopted until 1998.)	1985 Code of Ethics (Australian Anthropological Society (AAS).) (In 1981, the AAS formed an Ethics Committee to draw up a Code of Ethics. Peter Sutton drafted a Code (see Sutton, 1986) which was revised and finally adopted in 1985. For further historical details, see AAS, 2012.)
Great Britain	2009 Code of Ethics and Conduct (British Psychological Society)	2002 Statement of Ethical Practice (British Sociological Association)	1999 Ethical Guidelines for Good Research Practice (Association of Social Anthropologists of the UK and Commonwealth)
Germany	1998 Ethische Richtlinien (Deutsche Gesellschaft für Psychologie)	1992 Ethik-Kodex (Deutsche Gesellschaft für Soziologie)	2009 'Frankfurter Erklärung' zur Ethik in der Ethnologie (Deutsche Gesellschaft für Völkerkunde)

communities in the United States. The Australian, Canadian, and European codes refer to them considerably in style and content. In the following, these debates will be examined in a bit more detail.

Psychology

Within the SBS, the field of psychology in the US was the first discipline to deal extensively with ethical questions. One reason for this early engagement might be the strong academic networks between medicine and psychology during the first half of the twentieth century. Moreover, many psychologists were involved in the treatment of World War II soldiers. They were asked to determine the draft eligibility of prospective soldiers or care for their mental health after their return from the field. Ethical dilemmas occurred quite frequently (Fisher, 2012, p. 3).

In 1940, a Committee *on Scientific and Professional Ethics* recommended the election of a Standing Committee and the release of a professional code to the *American Psychological Association* (APA). In retrospect, U.S. psychologist Nicholas Hobbs (1948) notes five motives for the interest of the community in a professional code of ethics: (1) "a growing sense of professional unity," (2) the need "to ensure public welfare, (3) to promote sound relationships with other professions, (4) to reduce intra-group misunderstandings, and (5) to promote professional standing of the group as a whole" (p. 80).

In 1947, the APA appointed the first *Standing Committee on Ethical Standards for Psychology* (chaired by Edward Tolman). It drafted a code of conduct and circulated it for broad discussion within the professional community (see Hobbs, 1948) before its final release in 1953. The procedure (proposed by Nicholas Hobbs (1948), a member of the committee) was highly participatory and drew from psychological insights to group dynamics and motives for ethical behavior. The goal was to "develop a technique which will be effective in modifying human behavior" (Hobbs, 1948, p. 82) and help to ethically imporove the professional conduct of psychologists. The code was based on 1000 reports of APA members describing and discussing ethically relevant situations and experiences in their professional life. From these reports, the Committee distilled a long and case-oriented code draft and played it back to the members for further revision. In 1959, it was revised and compressed, got more comprehensive, and then consisted of 18 principles and a preamble.

After a long period of minor revisions and adaptations to new fields of research and new methods, the APA Code was substantially revised in 1992. Since that time, the code distinguishes *aspirational principles* from 180 *specific ethical standards*. The principles are very general and meant to represent the foundational values of the profession, while the standards are meant to be distinct enough to serve as a basis for enforceable decisions by the APA and other Ethical Boards. In 1996, the APA Ethics Committee appointed an Ethics Code Task Force (chaired by Celia B. Fisher) in order to prepare another major revision of the code (Fisher, 2012, p. 6). The revised version was again subjected to a major participatory process and released in 2002. Apart from some new provisions concerning methodical innovations, a wider range of addressees, and some considerations related to the Internet, its major achievement was a higher level of concreteness, detail, and enforceability.

Sociology

After some scattered remarks and claims for regulation in earlier years, U.S. sociologists engaged in a broad discussion of ethical questions from the late 1950s on. The main impulse came from a number of controversial studies, extensively debated in journals and at conferences. These debates are an interesting document for a process which prepares the release of ethical codes in the late 1960s and early 1970s and some of them will be considered in more detail below.

In 1961, the American Sociological Association (ASA) appointed a Committee on Professional Ethics ('COPE,' chaired by Robert C. Angell) in order to discuss ethical issues systematically. Due to fundamental controversies, a new Committee was appointed in 1967 (chaired by Edgar A. Schuler), with the mission to formulate a statement on ethics for sociological research. After several revisions, the ASA Code of Ethics, a Council Preamble, and a Committee Preamble were approved by the members in 1971. The Committee Preamble formulated general statements on the identity of sociology as a profession and the nature of its Code of Ethics. It considered the fact that a lot of sociologists did not agree on the necessity of the Code of Ethics (e.g., Becker, 1964) and explicitly compared the development of this Code to the development of Common Law: based on cases from which principles are drawn slowly and carefully (Schuler, 1969: 317). The Code itself was rather short and vague, focusing (very generally) on the subjects' right to privacy, confidentiality, and protection from personal harm; on the researchers' duty of objectivity and integrity; and on the declaration of sources of financial support. Apart from a rather general claim in the Council's Preamble not to "manipulate persons to serve their quest for truth" (p. 318), the question of disguised observation – a highly controversial topic at that time – was avoided. The code got substantially revised in 1984 and 1997. The 1997 revision was preceded by 3 years of discussion within the COPE and aimed at a clarification of style, improvement of enforcement tools, and accordance with the new requirements of granting agencies. At the 2014 ASA meeting in San Francisco, the current Executive Officer suggested to revisit the Code of Ethics again. A committee has been formed.

Anthropology

The debate on research ethics in anthropology also started within the U.S. community. In contrast to psychology and sociology, it was not primarily focused on the relationship between researcher and research participants but on sponsoring relationships. Due to its long-term character, anthropological and ethnological fieldwork often requires the approval and sponsoring of state or private authorities. Sometimes these authorities have specific interests in the area and tie their support to a scientific pursuit of these interests. Intervention may reach from the adjustment of research questions to an obligation to pass on politically sensitive research findings to the authorities and/or hold them back from public and

scientific community. In an early reaction to this problem, the Council of the American Anthropological Association (AAA) released a one-page Resolution on the Freedom of Publication in 1948. It dealt with the question of academic freedom in situations of external research funding and claimed freedom of interpretation and publication for anthropological research results. During the 1960s, the debate expanded significantly. The discipline got involved in several scandals around controversial political projects including anthropological research. The most prominent case is related to *Project Camelot* and will be discussed in further detail below.

In 1965, the AAA *Executive Board* (EB) sent a report to the *Council of Fellows* (COF) concerning 'secret research' and the allegedly unethical involvement of U.S. anthropology with state politics. The Council asked the Board to investigate accusations in detail and the Board founded a *Committee on Research Problems and Ethics*. Chair Ralph L. Beals presented a report (the so-called *Beal Report*) at the AAA plenary session in 1966 which led to the release of the first AAA code of ethics by the COF – the *Statement on Problems of Anthropological Research and Ethics* in 1967. One year later, an *Interim Committee on Ethics* was installed. It recommended the election of a *Standing Committee on Ethics* (COE) and presented a draft for an ethical code. Both suggestions were controversially discussed: a lot of AAA members considered them to be unnecessary or itself unethical. Nevertheless, the first official COE was elected in 1970 and released a code of ethics called *Principles of Professional Responsibility*, as well as a text on *Role and Function of the Committee on Ethics* in 1971. In the same year, another case of dubious connections between research and secret governmental plans came up – the 'Thailand case.' It provoked severe tensions between the COE and the EB, led to the foundation of an ad hoc committee (chaired by Margaret Mead) and divided the Association into two fractions. The *Mead Report* disburdened researchers in Thailand, stating that no violation of the 1967 statement had taken place. Still, the discussion remained controversial and emotional until the end of the Vietnam War in 1973.

Afterward, the emphasis of the COE shifted toward a micro-level, focusing on questions of informed consent, anonymization, plagiarism, and so on (Hill, 1987). The last revisions of the code took place in 1998, 2009, and 2012. Compared to the Codes in psychology and sociology, the AAA code is still rather short (app. 6 pages) and principle-oriented, and the matters for its enforcement are very restricted.

Leading Cases

The history of ethical codes in the SBS covers only a small – yet important – part of the history of ethical questions. Ethical debates do not start with codifications. Typically, they start with concerns, complaints, and convictions of scientists and laymen about alleged ethical wrongdoings. Therefore, an important part of the history of ethical questions is a *history of cases* which leads to discussions about ethical problems within a profession. The relevance of 'leading cases' – especially for the debate within the United States – is underlined by the plan to compliment the ASA Code of Ethics with a casebook in the late 1990s. In the following, some of the most prominent cases will be discussed. The choice does obviously neither claim for completeness nor for representativeness but it helps to understand the structure and style of discussions in the early stage of the debate.

The 1950s and 1960s were a high time for ethical debates on cases in the SBS. Apart from those discussed here, one might mention Alfred C. Kinsey on *Sexual Behavior in the Human Male/the Human Female* (1948/1953), Festinger/Riecken/Schachter: *When Prophecy Fails* (1956), Laud Humphreys *Tearoom Trade* (1970), Philip Zimbardos *Stanford Prison Experiment* (1971), and many others. Many of them provoked controversies in sociological, psychological, and/or anthropological journals and some of them still serve as reference points for arguments and reevaluations of research ethical questions. Altogether, these cases document a process of growing sensitivity toward ethical questions in the SBS, resulting in the release of ethical codes in the late 1960s and 1970s. This process has at least three interesting characteristics. First, a shift in ethical convictions: the idea that ethical considerations are subjective in nature and therefore no legitimate criteria for scientific work, shifted toward a notion of professional ethics, binding on other than subjective grounds. Second, a step back from the conviction that scientific progress justifies all methods of investigation. Increasingly, ethical qualities reached the status of an important criterion for good research. And third, growing differentiation: the conviction formed that there is more than one kind of ethically relevant research relationship and more than one type of ethical responsibility. Different kinds of secrecy, grades of anonymization, kinds of informed consent, etc., started to be distinguished (see e.g. Roth, 1962).

The Springdale Case (1958)

The Springdale case became one of the leading cases for questions of anonymization. It refers to a community study by Arthur J. Vidich and Joseph Bensman (*Small Towns in Mass Societies*, 1958), reporting on a fictitious town in rich ethnographic detail. The material stems from fieldwork in Ithaca, where Vidich was engaged in another research project. He considered his notes and other material from the project to be valuable and decided to write a book on the structure and organization of the community. He tried to anonymize town and community members, but the true identity of 'Springdale' was easily revealed.

The book received broad attention, and many colleagues expressed concern about the ethical implications of the study. William Foote Whyte (1958) launched a debate on the case in *Human Organization*, resulting in a big discussion on professional ethics. Apart from failed anonymization, Vidich and Bensman were attacked for disguised investigations and for using material from the project without permission from the project leaders.

In their first response, Vidich and Bensman refused to concede any ethical problems in their research and claimed to have acted for the sake of science in every respect. They argued for the impossibility of further anonymization without changing the story (and its sociological punch line) completely. They underlined the importance of the study for the field of community studies and claimed that everything they said about the town and its members was common sense in

Springdale. Among others, Whyte (1958) pointed toward the difference between orally passed on local knowledge and written accounts with the pledge of scientific evidence. The second edition of the book (Vidich and Bensman, 1968) contains supplementary materials and a discussion of methodological and ethical questions. In his 2009 autobiography, Vidich also reports about the circumstances and faith of the study at length (Chapter 8).

Alcoholics Anonymous (1960)

John Lofland's and Robert Lejeune's study on *Alcoholics Anonymous* (AA) became a leading case on problems of secret observation. In 1959, the two sociologists held a research seminar at Columbia University and sent some of their graduate students to AA gatherings for participant observation. The observers concealed their identity as researchers and pretended to be newcomers to the group. Their dressing and behavior was planned and rehearsed in detail before they entered the field. After each meeting, the students took field notes and discussed their observations with the teachers. The use of a hidden recorder was considered, but dropped for reasons of feasibility. In 1960, Lofland and Lejeune sent a report of their main findings and some methodological reflections to the journal *Social Problems* (Lofland and Lejeune, 1960).

In the next issue, Fred Davis (1961) accused the authors of "premediated deception" (p. 364), lack of informed consent, and "tacit disrespect shown for AA's values" (p. 364). Moreover, he took the case as an example of a general moral dilemma of sociological research: the exploitation of an 'out-of-research-role' in order to elicit information for research purposes. Altogether, he considered the approach of Lofland and Lejeune to be a violation of the "collective conscience of the community, if not that of the profession," altogether "less than human (sic), and hence unworthy of a discipline which, whatever else it represents itself as, also calls itself by that name" (p. 365). Lofland's reply to this critique took a rather radical stand against Davis' allegations: "our obligation to science," Lofland wrote, "is the objective, full and unbiased execution and reporting of observation." Ethical considerations were therefore "simply not part of the legitimate criteria for judging research. Therefore, *as* scientists and professionals, we have no reason to be concerned with Mr. Davis' opinions of our personal moral standards." (p. 366) In this article, Lofland disputed the merits of professional research ethics altogether. Since the generalization of individual moral convictions can lead to absurd laws of conduct, he argued, moral dilemmas of researchers were completely up to the individual and "should not be solved by the intervention of the profession at large or other professionals speaking personally" (p. 367). (Some years later, Lofland changed his opinion on this matter.)

Lofland's reaction provoked a broad discussion within the U.S. sociological community. In 1962, Julius A. Roth tried to structure the debate in a letter to the editor of *Social Problems*. He distinguished different layers of consideration (size of the observed group, intimacy of pre-research relationship, level of organization and power of the observed group, systematic character of research, etc.) and concurring moral intuitions (outcome- versus principle-oriented) concerning secret observation. Interestingly, Roth did not call for a code of ethics. On the contrary he stated: "We are more likely to develop a useful and satisfying working ethic by analyzing the research process of the sociologist himself than by drawing up written codes of ethics which merely perpetuate current moral biases and restrict rather than aid further ethical development" (p. 284).

In 1965, Kai T. Erikson took up on the topic with another text in *Social Problems*. He called for a distinction between 'personal morality' and 'professional ethics' and interpreted the latter as a contract between professionals. This contract implies responsibilities in relationships of the researcher and (1) his subjects, (2) his colleagues, (3) his students (who are asked to do the work), and (4) his data. Disguised observation, Erikson concluded, implies problems in all of these dimensions. Moreover, Erikson suggested to distinguish between the concealment of one's identity as a researcher and one's research goals and its deliberate misrepresentation, the latter being unethical in any case. Erikson refers to other cases (like Springdale) as well and suggests to take first steps toward a "general posture on the question of disguised participant observation" (p. 259).

The Milgram Experiment (1961)

The Milgram Experiment is one of the most famous experiments in social psychology and still serves as a reference case for informed consent and the risk to inflict moral and psychological harm to research participants. It started in 1961, during the trial on Adolf Eichmann. With his experiments, U.S. psychologist Stanley Milgram wanted to find out what makes people obey to an authority, if they are asked to act against their personal moral convictions. He tried to test how much pain people were prepared to inflict to another person in mere situational obedience to an authority. He deceived the participants about the real research question and asked them to play the part of a teacher who tries to improve his/her student's results by inflicting electroshocks for each mistake. In fact, the alleged 'students' were part of the research team and no electroshocks got ever displayed. The results were unexpected: 65% of the participants were prepared to administer a 450 V shock, although the alleged students claimed to stop the experiment and displayed severe pain. (For details on the experiment, see the chapter on *Obedience*.)

Despite the huge interest in the results by colleagues and public (Milgram's findings are still considered as a landmark in the field of obedience studies), it was strongly contested for the ethical implications of the research setting. The most prominent and insistent critic was Diana Baumrind, a psychologist in Berkeley. After the 1963 publication of some of Milgram's findings in the *Journal of Abnormal and Social Psychology*, Baumrind wrote a comment in the *American Psychologist* (1964), addressing four major ethical problems of the experimental setting: (1) The participants did not know which kind of study they were engaging in; (2) The participants were subjected to extreme stress (heavy sweating, trembling, stuttering, and nervous laughter were reported). They might have suffered psychological harm and an uneasiness to trust authorities as a result of their participation in the experiment; (3) The participants were manipulated, discomforted, and embarrassed during the experiment. Thereby they were (4) denied their dignity and their right not to be

used as a mere purpose for the researchers' (secret) goals. According to Baumrind, all of these problems can – if not addressed properly – lead to a decline in public image of psychology and is therefore ethically problematic toward the profession and colleagues. She calls for full information about the possible risks and systematic care for eventual harms of participants in the aftermath.

In his response, Milgram (1964) claimed that stress as well as indignation of the research participants were neither intended nor accepted but came completely unexpected. To refrain from the risk of unexpected reactions of research participants, Milgram argues, would mean to refrain from scientific inquiry. He also presented the results from a questionnaire among the participants, indicating that 84% of the participants were retrospectively glad to have participated in the experiment and only 1.3% said that they were either sorry or very sorry to have participated. Up to one year after the experiment, participants were provided with results, appreciation for their effort, and the opportunity to talk about their reactions. Milgram's reply does not directly address Baumrind's concern about the concealment of the research question.

Project Camelot (1964–65)

Project Camelot was the code for a social science research project initiated by the U.S. Army in 1964. Conceived by a Special Operation Research Office in the American University of Washington D.C. and Research and Development Unit of the U.S. Army, the management was confided to Rex Hopper, a scholar with expertise on revolutionary movements in Latin America. The goal of the project was to study the cultural, economic, and political conditions of internal war by means of systems analysis and with an international team of social science researchers. According to one of its first documents (a letter of invitation to participate, mailed to a selected number of international researchers), Project Camelot was meant "to determine the feasibility of developing a general social systems model which would make it possible to predict and influence politically significant aspects of social change in the developing nations of the world" (1964, quoted from Horowitz, 1967, p. 4f.). Due to several miscommunications, breaches of secrecy, and diplomatic entanglements the project got stopped before it really started. Nevertheless, the Camelot affair caused big discussion within academia, the military, the public, and the state officials of several countries (especially Chile and the United States). Some of the involved anthropologists got suspected of espionage for the U.S. Government or unwittingly supporting political interventions against local populations. More generally the question came up, if and under which circumstances state funding of and/or political interests in research are likely to restrict scientific freedom to an unbearable extent. The case was discussed in U.S. Congress hearings and received broad attention by the media as well as professional academic organizations. For details on the course of events, see Horowitz, 1967.

After its termination, the project lost public interest but remained a hot topic among social scientists for many years. Freedom of scientific inquiry in a situation of governmental funding and military supervision, responsibility for research data, and political implications of research were extensively debated with regard to Project Camelot. Until today, it as a reference case for ethical dilemmas of state-funded research. It significantly influenced the release of the first AAA Ethical Code in 1965 and was also quoted in connection with the ASA Code of Ethics of 1969.

Other Relevant Factors

So far, this entry focused on the foundation of ethical codes and some leading cases in psychology, sociology, and anthropology. Of course, this is only part of the story. In order to give an idea of the complexity of the development as a whole, this last section addresses some additional factors that are important for the history of ethical questions in the SBS.

The history of research ethics in a discipline is closely linked to the *history of its research methods*. Experimental research designs are more likely to trigger problems of informed consent and the risk of psychological, physical, and moral harm, ethnographies often touch on problems of disguised observation and anonymization, and expensive methods requiring external funding (like extensive fieldwork or large-scale experiments) are likely to get in trouble with questions of tortious influence and conflict of interests. New methods go along with new ethical problems, and the import of methods from other disciplines comes together with the ethical problems related to it.

The history of research ethics is also strongly related to the *history of the disciplines* and their academic organization. Ethical questions became more and more urgent with the rising number of researchers, the increase of public research funding, and the growing public interest in the results of this research.

The history of research ethics is also linked to the *history of research funding*. The development of ethical codes of conduct historically coincides (at least in the United States) with the development of large-scale research funding programs. Apart from ethical problems linked to funded research (see the discussion above), ethical nonobjection also became one of the leading criteria for research funding institutions. Today, many research funding agencies require a certificate of harmlessness by a professional ethics committee. Accordingly, universities are required to install such committees and release a code that guides its work.

The history of research ethics is also connected to the *history of academic journals*, where most of the debates on ethical questions took and still take place. A platform for frequent professional exchange enables quick, intense, and transparent debates. For the development of collective ethical convictions, standards, and codes, this kind of discussion is crucial. An analysis of the most prominent cases shows that the debate often follows a three-step pattern: (1) breach of an unsaid ethical principle in a particular research case, (2) accusation and discussion of the case in professional journals and/or in public, and (3) enacting or modification of a professional code of ethics.

Finally, the history of research ethics is closely connected to the *history of scientific trust*. The fast-growing development of research ethics in the SBS took place during a time of public disappointment with the merits of science after World War II. The public as well as scholars started to look more closely at the

ethical quality of academic research. In the late 1960s, student revolts as well as the upcoming science studies supported this critical approach and further decomposed the holy grail of science. This situation was remarkably different from the early twentieth century, when most people (scholars as well as nonacademics) held a strong belief in the powers of scientific reasoning (for a similar argument, see Lock, 1995, p. 519).

Problems of research ethics are always located in a *broad field of norms and interests*, not all of them being ethical in nature (see Filstead, 1970, p. 266). The history of research ethics is always embedded in the history of political, professional, and institutional norms and interests.

Ethical convictions change over time. What was considered to be ethically neutral at one time can be considered to be ethically unbearable at another; minor ethical concerns can significantly grow in importance. The cases discussed above have shown that quite clearly. Therefore, the history of research ethics is not only a history of codification or changing moral sentiments of academics but also a history of moral change on a broader scale.

Conclusion

Ethical questions in the SBS started to unfold in the United States during the 1940s and 1950s and came to a provisional climax in the late 1960s and early 1970s. During this time, several ethical codes were released and books on the matter published (e.g., Horowitz, 1967; Filstead, 1970). The debate brought about considerable shifts in perspective in the professional communities. In the beginning, the debate was highly controversial and emotional, revealing both the significance of ethical questions for the community and the wide range of opinions on how they can be solved. In some of the early case discussions, scholars argued against ethical considerations with reference to the 'moral neutrality of research.' With the release of ethical codes and installation of ethical boards in the leading professional associations and universities, this view got more and more contested.

Throughout the 1970s and 1980s, the debates on research ethics slowly flashed over from the United States to Canada and Europe. Some scholarly associations used the codes of their U.S. colleagues before releasing their own. In Europe, the first ethical codes were released during the early 1990s. The 1990s was also a high time for research ethics in the United States, where a lot of ethical codes were considerably reviewed.

Ethical Turn in International Development

Eleanor Fisher, University of Reading, Reading, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The ethical turn in international development relates to a tendency to question the deleterious impact of international development action on local populations and environment. As a consequence, new courses of action are proposed in order to generate socially just and environmentally sustainable global change. This tendency is most prominent in relation to the development impacts of globalization of production and trade but also appears across a wide range of development sectors.

International development relates to change in living standards by developing countries through the elimination of poverty and the creation of institutional environments conducive to material improvement. It is a broad field encompassing topics as wide ranging as economics, politics, social transformation, overseas development assistance, health, infrastructure, education, governance, humanitarian relief, environmental change, human rights, and gender equality. Ethical concerns enter into all of these aspects. However an 'ethical turn' emerges most strongly out of the globalization of production and trade and is linked to demand by citizen-consumers to know where and how products and services originate, the conditions under which they have been produced and traded, and the sustainability of these processes.

The ethical turn does not refer to coherent shared politics, values, or practices, but points to a tendency within international development, which emphasizes consideration of peoples' quality of life in terms of healthy, secure, and sustainable living and work environments, and of the impact of development processes on people and the planet. Thus, the ethical turn has been consolidated through diverse international campaigns over labor rights, the mineral trade and conflict, food quality, animal welfare, health concerns, natural resource depletion, and environmental sustainability. Increasingly, citizen-consumers demand that ethical standards are upheld by companies and organizations producing and selling products and services from developing countries; they also demand that governments and international organizations demonstrate leadership in setting ethical development agendas and in ensuring ethical development practice.

Globalization and Market Integration

Stiglitz (2006) conceives globalization as encompassing the increased integration of people and countries due to a change in information communication technologies, reduction in transportation costs, and the removal of cross-border barriers to the flow of goods, services, and capital. One aspect of globalization is an increasingly interdependent global market, as described by Kingsbury (2012). Another aspect of globalization, linked also to neoliberal capitalism, is a transformation in established orthodoxies on the relationship between the state, market, and society. The changing power of supra- and substate authorities, and the influence of nongovernmental organizations and companies mean a multiplicity of social actors and power regimes come together beyond the nation-state (Grande and Pauly, 2005). These processes are illustrated by Fisher (2012) in a case study of Wales, the world's first Fair Trade Nation. In the Welsh example international development practice is driven by government's close relationship to civil society organizations and businesses promoting ethical trade.

In a global era driven by neoliberal capitalism, in which the centrality of the market is championed, the power of transnational corporations comes to the fore. This corporate power has potential for adverse social and environmental effects, as companies seek to source products and services at the lowest cost without considering broader externalities. Impoverished people may be paid a pittance for their labor and may work in conditions where negative impact on life well-being can be profound (Brown, 2000). Linked to this are questions over business standards in developing countries and who holds multinational corporations to account for their actions.

Associated with changing relationships between state, market, and society is the rise of organizations that are explicitly in favor of globalization and play contradictory roles in the ethical turn in international development – both by acting as standard bearers for human development and human rights and, conversely, through stimulating unintended social protest in response to their actions. These organizations include the World Trade Organization (WTO), the International Monetary Fund (IMF), the World Bank, the Organization for Economic Cooperation and Development (OECD), and the United Nations (UN). The WTO, IMF, OECD, and World Bank focus on aspects of economic development and the UN and its agencies on global security through the political, humanitarian, and social aspects of global development (Kingbury, 2012).

The Governance of Ethics through Voluntary Regulation

Voluntary regulation has emerged as an important mechanism for introducing ethical standards into aspects of international development. As Brunsson and Jacobsson (2000) describe, standards are rules that identify the course of action that those who adopt them should follow. The state has historically been the main body that promotes standards for regulation, often but not always backed by legislation. However, as global governance processes have become more complex, and in the context of an ideological emphasis on the neoliberal market as opposed to state control, voluntary regulation has become increasingly prominent across a wide range of development sectors. Standards associated with voluntary regulation perform

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10153-9

two key functions: product differentiation and risk management. They are part of a wider 'tripartite standards regime,' which includes standard setting, certification, and accreditation, and reflects evolving governance processes in which state-based systems have shifted to networks of regulation that incorporate state, corporate, and nongovernmental actors (Loconto and Busch, 2010). Against this background an important issue is how local development actors, interests, and values shape the effect of standards on processes of development transformation relevant to ethical issues (Viteri and Arce, 2013).

Both transnational social movement organizations and corporate actors promote the use of voluntary standards as mechanisms for ensuring that ethical issues are taken into account in international development in response to concerns by citizen-consumers about safety, quality, ethics, and production conditions (SC of the SKASC, 2012). This has led to a burgeoning of standards, certification, and product labels, as illustrated by information held by the International Trade Centre on over 100 voluntary standards (www.standardsmap.org).

Global development organizations, such as UN agencies, also play important roles in leadership for global standards. This leadership is reflected in legally binding agreements, such as some labor standards promoted by the International Labor Organization (e.g., on child labor) and the Minemata Convention on Mercury, a global treaty to protect human health and the environment from the adverse effects of mercury, whose adoption has been led by United Nations' Environment Programme through the Global Mercury Partnership and Intergovernmental Negotiation Committee. Standards also relate to nonmandatory guidance, such as the OECD's 2011 Due Diligence Guidance for Responsible Supply Chains of Minerals from Conflict-Affected and High-Risk Areas.

Corporate Social Responsibility

Corporate social responsibility has been adopted by business as an approach to international development that brings ethical issues to the fore. It focuses on consideration of the social and environmental impacts of business activity and how they can be mitigated. Blowfield (2005) argues that the incorporation of corporate social responsibility as an approach to international development raises crucial questions about who benefits and in what ways; in particular, is it used as a vehicle for certain interest groups to redefine the meaning of international development success? In examining this question and the degree to which business focuses on instrumental outcomes in development as opposed to intrinsic gains, Edward and Tallontire (2009) outline a model to examine businesses' role in development. To do this, the model presents two continuums: one focuses on the business–society relationship and the other on concepts of development (Tallontire, and Nelson 2013). Strength of this model is that it provides a means to observe and analyze the changing role of business in development, rather than positing ideal positions for or against. Examples of empirical analyses of the relationship between corporate social responsibility and development and relevant ethical issues are provided in an edited collection by Barrientos and Dolan (2006), examining how ethical sourcing has entered mainstream food retailing and whether it can address problems facing workers and producers in the global food system.

Social Movements and Public Campaigns

Nongovernmental organizations, trade unions, and the many different actors that are part of civil society have become increasingly important in international advocacy over ethical issues in developing countries, influencing policies, and affecting the contexts in which they are made. Micheletti et al. (2006) suggest that the global market in particular becomes a site for ethics and citizen action. They propose the idea of political consumption in which the market becomes a site for politics, expressing political values beyond traditional markers of value – price, taste, and quality. This can be seen in historically prominent international campaigns, such as the movement against apartheid in South Africa between 1959 and 1994, student protests in the 1970s over the multinational corporation Nestle's sale of formula milk to mothers in the developing world, and violent demonstrations with diverse motivation in reaction to meetings of the WTO and Group of Eight (G8) leaders of the world's most powerful countries. For Kriesberg (1997), these and similar campaigns reflect the rise of transnational social movement organizations, made possible by democratization, global integration, and the convergence and diffusion of values.

Social movements promoting ethical causes in international development draw complex linkages between a wide range of development issues and actions that can be taken by government, business, and society. Two contrasting examples illustrate these processes.

The first example comes from the African mining sector, which in the twenty-first century is a crucial driver for the 'mineralization' of economies and societies across the African continent (Bryceson et al., 2014). Emphasis on ethical issues in African mining has been stimulated by high-profile international campaigns on 'conflict' or 'blood' diamonds and minerals – where profits from the mineral trade fuel violent conflict – and by corporations worried about reputational damage as result of the negative social and environmental impacts of mining. These issues have brought traceability and accountability to the fore in the mineral trade. Focusing on artisanal gold production for fair trade markets, Fisher and Childs (2014) provide a case study on how voluntary regulation on ethical standards has entered into mineral production and trade in sub-Saharan Africa. They illustrate how a large number of ethical standards have been developed to certify the absence of conflict, good labor conditions, mitigation of environmental impacts, and development benefits for artisanal producers. These standards combine voluntary initiatives, e.g., the Fairtrade and Fairmined Gold Standard, with mandatory legislation, e.g., the United States Dodd–Frank Wall Street Reform and Protection Act, and nonmandatory guidance by international organizations, e.g., UN Guidelines on Due Diligence.

An important question is whether ethical standards, such as the Fairtrade and Fairmined Gold Standard, create new opportunities for market-led development transformation or whether they reinforce established patterns of power and

inequality with potentially detrimental and unintended consequences for artisanal producers or workers in large-scale mining operations. Fisher and Childs propose that Fairtrade has the potential to benefit artisanal gold producers, but suggest that there are significant impediments in practice to this occurring in ways that challenge established power and market relations to the benefit of the most marginalized in mining communities. See also Lompo and Trani (2013), who examine corporate social responsibility and development in the oil sector, presenting a case from Nigeria.

A second example of linkages between ethical issues, development, and actions taken by social movement organizations is from the Latin American health sector. As countries develop, governments face the problem of what policy response to make to noncommunicable diseases. Among these diseases are the consequences of poisoning from reliance on use of dangerous pesticides in food crop production and subsequent deleterious effects on human health. Sherwood et al. (2013) examine pesticide use, noncommunicable diseases, and social action on the ethics of development in Ecuador. They outline three significant policy developments in modern food supply: making food accessible to the whole population, the arrival of energy-compact food products, and industrial food production – all have been associated with agricultural productivity reliant on high pesticide use. One unintended consequence relates to rising levels of obesity due to the high sugar and fat content of the food products. Challenging the use of pesticides and arguing for the need for healthier food consumption are social movement organizations, which propose alternatives to the dominant food regime. Sherwood et al. (2013) argue that the sheer violence of the pesticide technology has captured the public imagination, generating challenges to seemingly all-powerful and impervious food ideologies and business interests. An outcome of the ethical countermovement was the introduction of legislative measures to eliminate highly toxic pesticides.

Examples from the African mining sector and Latin American health sector contrast markedly; nonetheless both highlight how international development issues generate ethical concerns and how social actors from civil society, government, and business respond to these concerns in ways that seek to challenge established practices and power relations in the favor of local people.

Conclusion

The ethical turn in international development relates to a tendency to question the deleterious impact of international development action on local populations and environment. As a consequence, new courses of action are proposed in order to generate socially just and environmentally sustainable global change. This tendency is most prominent in relation to the globalization of production and trade, but also appears across a wide range of development sectors. In taking action on ethical issues, the changing dynamics between civil society, state, and market become apparent. The power of transnational corporations comes to the fore, but so does the ability of transnational social movement organizations to challenge the status quo in terms of power hierarchies and accepted values, often through using the market as a site to express the politics of consumption but also by lobbying governments and global institutions.

Ethics and Psychiatry

Allen R Dyer and Eindra K Khin, The George Washington University, Washington, DC, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Psychiatry is a profession defined and guided by well-established norms dating back to the Hippocratic Oath and carefully delineated by the standards of modern biomedical ethics and professionalism. Key principles, such as beneficence (confidentiality), autonomy (informed consent), nonmaleficence, and justice provide bases for clinical judgment in specific contexts. Commercialism in health care introduces potential conflicts for the professional, whose primary allegiances are to the patient and those served. Several new challenges are faced by psychiatrists and other professionals in the twenty-first century. These include telemedicine, electronic health records, and social networks/social media.

Ethical codes and traditions are important in defining the norms of professional conduct and even what it means to be a profession. Insofar as ethics deals with intellectual attempts to understand right and wrong (reason) as well as the affective impact of struggling with moral issues (emotion), psychiatric thinking offers an important perspective on ethics. This article deals with both ethics in psychiatry and psychiatry's contributions to ethics. Although changes in society and especially the recent advent of managed care have led to challenges to professional identity, the Hippocratic tradition continues to provide a perspective of enduring values that calls into question many of the assumptions of modern culture and transcends the pressures of political expediency.

Ethics concerns what is right and what is wrong. It is often used synonymously with morality, but sometimes a distinction is made between ethics, the systematic approach to understanding right and wrong, and morality, the forces which govern right conduct. Ethics is central to human experience, and plays a vital role in the profession of psychiatry. In a time of cultural change, the appeal to ethics can help to resolve conflicts of both civic life and self-understanding. Often ethical principles are used in an attempt to find a common ground or a 'higher ground' for resolving disputes or to find a basis for acting in a dilemma.

Ethical codes and traditions are important in defining the norms of professional conduct and even what it means to be a profession. Insofar as ethics deals with intellectual attempts to understand right and wrong (reason) as well as the affective impact of struggling with moral issues (emotion), psychiatric thinking offers an important perspective on ethics. This article deals with both ethics in psychiatry and psychiatry's contributions to ethics.

Types of Ethical Theories

There is in ethics, a constant tension between rule-based (deontological) approaches and approaches that appeal to principle (teleological). Deontological ethical theories maintain that there are rules of action with moral validity independent of the consequences that require adherence, such as keeping a promise, maintaining justice, or following a commandment of God or the state. Teleological ethical theories are based on the principle of utility (utilitarianism) or beneficence, which proposes that the ultimate moral standard is the general happiness of all people concerned, or the greatest net balance of good over evil ('the greatest good for the greatest number'). Situation ethics represents another form of ethical reasoning, called the consequentialist approach, in which an action is judged to be morally right or wrong by assessing the consequences of the action. Much of clinical medicine is consequentialist in that the goodness of actions is judged by their outcomes.

Ethics of Virtue and Character

Both teleological and deontological approaches to ethics have one serious shortcoming. They depend on the activities of the rational mind of a motivated moral agent to apprehend right and wrong. Moral philosophers and psychiatrists alike appreciate that not everyone is motivated to be moral; that even good people sometimes do bad things; and that people are capable of rationalizing self-interest (Hauerwas, 1977, 1981; Pincoffs, 1971, 1980).

A delineation of obligations, however essential, is not the whole picture of ethics. Virtue, character, and integrity are every bit as important in understanding right conduct. For the professions especially, integrity in concrete situations is the hallmark of virtuous life.

A Brief History of Medical Ethics

The ethical traditions of the medical profession originate in the fourth century BC with the Oath of Hippocrates. This oath, sworn by healer–craftsmen, has come to symbolize the ethical ideals of the medical profession. In the nineteenth century, first the British Medical Association, and subsequently the American Medical Association (AMA) and professional organizations in other countries began to adopt formal codes of ethics modeled on the principles of the Hippocratic Oath.

By the mid-1960s, the values underlying the doctor–patient relationship began to change. The most notable factor was the emergence of new technologies, which began to change the way we thought about medicine and even what it meant to be human: genetic engineering, organ transplantation, advanced life support, safe abortion and birth control, and medical and

surgical treatments based on clinical research. No longer was medical care primarily palliative. No longer could it be assumed that the patient would necessarily want what the doctor might offer (Dyer, 1997a,b).

Also in this era, several social movements began to change the way society thought about assumed relationships, with an increased emphasis on the right of the autonomous person to self-determination. Informed consent and autonomy came to be the keys to medical ethics and medical decision-making. Medical ethics in this era became bioethics, as it came to be realized that the decisions in medicine were decisions in which society had a stake.

By the 1970s, economics increasingly became a part of thinking about ethics. Allocation of resources became a concern, and the question was often asked, "Could health costs be contained without rationing care?" The principle of justice eventually superseded beneficence and autonomy in ethical discourse, with an emphasis on fair distribution of medical resources.

The Ethics of Advertising

Most physicians are not inclined to seek patients though advertising. Health care organizations, however, may make their appeal through advertising, especially in a market-driven health care economy. The 1957 version of the AMA *Principles* prohibited 'solicitation' of patients, by which was meant 'obtaining patients by deception,' or making false claims (AMA, 1957). After the Supreme Court decision Federal Trade Commission (FTC) versus AMA (Greenhouse, 1982), professional organizations such as the AMA can no longer formally constrain physicians from advertising.

Advertising has two basic goals: (1) dissemination of information and (2) product differentiation. For physicians, providing information about services offered and fees charged is consistent with patient benefit, but attempts to differentiate the product are suspect. Licensing, accrediting, and credentialing organizations assume the role of maintaining standards. Beyond the activities of individual practitioners, the larger ethical question for advertising is truthfulness. Notable is the advertising of unhealthy products such as tobacco products and alcohol. Much advertising is antithetical to professional goals of patient benefit (Dyer, 1995, 1997a,b).

The Place of Ethics in the Definition of a Profession

What differentiates a profession from a trade? What makes medicine a profession? The emphasis on the commerce of technology in medicine in recent years may obscure the centrality of an ethical attitude toward the patient, which has traditionally been considered to be the defining feature of a professional life.

A profession may be defined by (1) its knowledge, technology, and expertise, or (2) its ethics or values. The habits of modern thought might lead us to believe that this is an either–or choice. Clearly for psychiatry, as for most of medicine, allopathic technologies such as drugs and procedures have become important and perhaps even central in some people's minds. The recent primary care thrust has reopened consideration of a more holistic approach to healing, including talking. Ethics is more fundamental to professional definition than technology. Technology is useful as long as it serves ethical ends but not as an end in itself. Knowledge, technology, and expertise are not commodities to be bartered in the marketplace, but skills which may be used to ethical ends under the purview of professional values.

The Hippocratic Oath and the Hippocratic Tradition

The Hippocratic Oath is a remarkable document, not so much because it answers the ethical questions posed by modern medicine, but because it frames those questions. It articulates principles, notably the principle of patient benefit, which is often helpful to physicians in sorting out where their allegiances lie. Taken together with its corollary, the principle of nonmaleficence (*Primum non nocere*, first do no harm), the principle of beneficence puts the patient at the center of ethical decision-making. The Hippocratic Oath provides an ethical perspective that calls into questions many of the assumptions of modern culture and transcends the pressures of political expediency.

The Contemporary Relevance of the Hippocratic Oath

A reading of the Hippocratic Oath reveals many phrases, which responsible physicians might not want to follow literally. Medicine was delineated as a higher calling, a covenant with the gods. The Oath provided a relationship with a like-minded family of individuals who shared certain values and self-understanding. It defined the physician's life in a beneficial relationship to those served. Its paternalism was questioned when society emphasized individualistic autonomy, but the Oath's emphasis on justice foreshadowed a larger concern for community interests.

The Hippocratic tradition has at various times and places served as an ethical reference external to immediate expediency, by which physicians may gauge their behavior and to which they can appeal (or by which they may be judged by their colleagues). For example, the World Psychiatric Association censured the practices of psychiatrists in the former Soviet Union and other Eastern European countries for the detention of political dissidents. Such mislabeling with psychiatric diagnoses is called the political abuse of psychiatry, for the profession is used for ends other than patient benefit (Bloch, 1991; Bloch and Reddaway, 1977). Such extreme abuses make a case, which is not always appreciated, for professions being autonomous organizations self-regulated by a code of ethics rather than serving the interests of society, which may be politically conflicted. The Hippocratic Oath is an ever-present reminder that acting in the interest of someone other than the patient creates a conflict, a conflict which is often experienced internally by the physician.

Honor in Medicine

The Hippocratic Oath speaks of honor, holiness, and purity. The good name and respect of both the practitioner and the profession are to be earned through consistent application of

the ethical principles, and the code provides guidance. Good conduct becomes 'characteristic' of the professional, and a code of conduct organizes one's thinking about good conduct both symbolically and in very practical matters.

The Fiduciary Principle

The doctor–patient relationship is spoken of sacredly as a fiduciary relationship, a relationship based on trust. That trust must be earned, at the least by the hard work required to acquire the skills necessary to apply the art. But it must also be earned by the consistent application of attentive response to the patient's needs, what we call 'responsibility.' Unlike law or business, where the trustee may act for the client, in medicine the physician must act with the patient and with the patient's consent, implying a partnership. That action may be paternalistic, but if that concern verges on control, the modern patient may well lose trust and confidence.

Hippocratic Oath for Psychiatrists

Maurice Levine (1972) articulated a Hippocratic Oath for psychiatrists with some unique insights about the values of this profession. His code articulates the importance of self-knowledge or at least self-awareness and constant self-scrutiny. He stresses the need to recognize in ourselves the feelings that patients can stir up, particularly seductive patients, and the importance of getting consultation (or supervision) not just in training but whenever it might be necessary. This is a useful reminder at times when many treatments are briefer and more biological, because many of the complaints of unethical conduct received by the American Psychiatric Association (APA) come from patients whose doctors did not sufficiently deal with their own feelings and acted out in treatment situations. Self-reflection is an important ethical tradition, not only in psychiatric and psychoanalytic circles, but throughout Western culture dating back to the Socratic admonition to 'Know thyself.'

Contemporary Codes of Ethics (AMA and APA)

When the AMA was founded in 1847, it adopted a code based largely on the Hippocratic principles of beneficence and honor. This code (*The Principles of Medical Ethics*) has been revised every few decades (most recently in 1957 and 1980). When the APA adopted its first code in 1973, it decided to use the AMA Principles *With Annotations Especially Applicable to Psychiatry*. The principles should be read teleologically, not deontologically as a list of rules. The requirement of honorable behavior of the physician goes to the physician's character and virtue and cannot be reduced to a list of rules. The physician must understand the principles in terms of a higher calling and act in accord with the dictates of conscience.

The APA (1993) may impose four possible sanctions for misconduct by a psychiatrist: admonishment (informal warning), reprimand (formal censure), suspension (not to exceed 5 years), and expulsion. In this sense, this code is minimalist but essential, serving as a tool for professional discipline. A psychiatrist should know what is specified in the code because he or she might be subject to sanctions. The modern physician should also understand the principles that underlie the code in order to be able to act in situations that have not been explicitly spelled out. The following discussions illustrate the constant tension between rule and principle and the importance of the physician striving for virtuous action.

Sexual Misconduct and Boundary Violations

Sexual contact with a patient is unethical. This is one of the least ambiguous sections of the ethical code. It is a tradition that goes back to the Oath of Hippocrates, which speaks of such conduct as 'mischief.' It is important for psychiatrists because the intimacy of the treatment activates strong feelings and fantasies in the doctor–patient relationship, the discussion of which may be essential to healing. In psychiatry especially, the nature of such feelings the patient may have for the doctor (transferences, i.e., derived from significant relationships in the past and activated in the treatment) and feelings the doctor may have for the patient (countertransferences) receive close scrutiny. They are no less important for other physicians, other therapists, or other professionals. It is sometimes argued that the reason sexual contact is proscribed is because of the power differential, an argument which applies equally to employers and employees, supervisors and supervisees, and teachers and students. Most basically, the importance of trust in the therapeutic relationship requires forbearance. As a rule, sexual contact with a patient is proscribed.

Those more legalistically inclined might wonder if erotic feelings might be acted on if the professional relationship were terminated. Transferences endure over time, so the interests of the patient–client could never be served by crossing this boundary. The most recent version of the APA *Annotations Applicable to Psychiatry* spells this out: "Sexual activity with a current or former patient is unethical." Other examples of boundary violations, which rest on similar considerations, are business relations with a patient, using the professional relationship for other contacts, or profiting from information gained from the therapeutic relationship.

The Boundary between Ethics and Law

Ethics and the law share a similar concern for right and wrong. But the ethical requirements of professionals do not coincide identically with the requirements of all citizens. The Oath of Hippocrates held physicians to a standard that was not required of all citizens. The AMA *Principles* and APA *Annotations* recognize this tension and expect physicians to 'respect the law' and 'seek changes in those requirements, which are contrary to the best interests of the patient.' Civil disobedience against unjust laws is a respected ethical tradition. A physician is a citizen whose professional role requires adherence to principles such as patient benefit above all.

Confidentiality

Confidentiality, understood as secrecy, in the doctor–patient relationship is one of the most fundamental principles of professional ethics. Confidentiality has its roots in the

confidence or trust that is placed in the physician and on which the treatment depends. It has become increasingly difficult to safeguard confidentiality. Insurance companies, managed care organizations, other providers, courts, and sometimes families claim a right to know what is going on in patients' treatments. The possibility of misuse of information from insurance data banks is a large issue. Confidentiality is one of the most fragile tenets in the contemporary era.

At times, principles may conflict. For example, the *Tarasoff* decision obligates a psychotherapist who has knowledge that a patient may intend harm to a third party to notify that third party of the potential risk. Mandatory reporting of suspected child abuse is another example in which the interest of the state in protecting children legally supersedes the physician's duty to maintain secrecy. In a larger context, the erosion of confidentiality threatens to undermine the possibility of a kind of therapy that requires developing openness to another person confident that what is disclosed is only for the patient's benefit.

The 'False Memory' Controversy

Much conflict has developed around the issue of therapists directing therapy to recover memories of childhood sexual abuse, which may not have occurred. In particular, there have been instances reported in which therapists used suggestive methods such as hypnosis in order to recover memories of past sexual abuse that were believed to be repressed. Alleged perpetrators of such abuse have been prosecuted and even jailed. Therapists' zeal about these issues may lead to unethical behavior, even with good intentions, with destructive results for their patients and families (Chodoff, 1999).

The Double Agent Problem

Double agents work both sides. There are situations in which the physician works for someone other than the patient, and there may be a conflict between the patient and the physician's employer resulting in a divided allegiance and compromised confidentiality. The classic case of this is the physician working for the military, trying to get soldiers back into combat. This is ethically analogous to treating the psychotic prisoner incompetent to face execution. The student health psychiatrist doing an evaluation for the dean or the psychiatrist doing a pre-arraignment examination have loyalties that go beyond the patient's best interest and which require at the least disclosure of the purpose of the examination and how the information will be used. Increasingly physicians working for corporations, managed care organizations, and government hospitals have interests, which radically transform the nature of the relationship between doctor and patient.

Fees, Billing, and Reimbursement

The financial arrangements for medical service strike at the heart of the ethical issues in how medicine is valued. Inevitably there must be some sort of exchange for the services rendered, and inescapably there must be some sort of feelings about the monetary transaction. In the dyadic doctor–patient relationship that is a very direct transaction, though it may be buffered by insurance companies, billing and collection processes. Patient benefit and fee-for-service have traditionally gone hand in hand, and the fee (alongside honor and duty, of course) has helped focus the physician's attention on whose benefit should receive attention. One of the general criticisms often leveled against traditional (Hippocratic) medical ethics is that it does not deal with the physician's larger obligations to society and particularly, to the distribution of medical services.

One financial arrangement in particular that sometimes questioned is the practice of charging for missed sessions. The APA *Annotations* has specifically addressed this and has said, "It is ethical for the psychiatrist to make a charge for a missed appointment when this falls within the terms of the specific contractual agreement with the patient" (Sect. 2, paragraph 6). The idea of patients having responsibility for the treatment and ultimately for their health and well-being is not something usually considered in medical ethics, but it goes beyond the idea of medicine as technology that the doctor delivers and stresses the patient's investment and commitment to the healing process.

Another financial arrangement that is addressed throughout the AMA *Opinions* and APA *Annotations* is fee splitting. Physicians should receive remuneration for the work they do, and they should obtain patients by referral based on the quality of their work and the reputation they earn in the eyes of satisfied patients and other physicians. Any incentive such as splitting the fee with a referring physician is considered unethical. It offers a temptation to place monetary gain above the best interest of the patient.

Informed Consent

An issue that has been receiving increasing attention recently is the importance of preserving patient autonomy and control in the context of medical decision-making and participation in research. Recent debate has occurred around the issue of whether patients with psychiatric illnesses are competent to give consent in such situations. The danger in such debate is that psychiatric patients can be further stigmatized with policies that are overprotective and confuse psychopathology with a generalized lack of competence. Efforts to educate patients regarding the nature of medical decisions and research projects should protect their rights by helping them to make decisions for themselves (Appelbaum, 1998).

Ethics and Health Care Financing

The current revolution in health care financing challenges many traditional assumptions of medical ethics. The most fundamental change is the departure from a dyadic doctor–patient relationship. Doctors in the new environment are being transformed into 'providers,' patients into 'consumers,' and any number of 'third parties' claim an interest in what goes on in that relationship.

In the economic model of marketplace transactions, much more is at stake than how the payment is to be allotted. The metaphor of health care as an industry radically transforms the healing process to physiological interventions that take place in a delimited period of time. Physicians become technicians, and

patients become recipients of technology, with both likely to be strangers to one another. Medicine is transformed from a human service into a commodity.

In the interest of efficiency or economy, these transformations might seem warranted, but the practices we are currently witnessing in the name of managed care must themselves be subjected to ethical scrutiny. Certainly much of what is going on is not ethically justifiable, nor does it serve the ends it was purported to serve. The transformation of medicine from a profession to a trade by the FTC was justified as a cost-saving measure on the grounds that increasing consumer choice (through advertising) would lower costs. The value placed on autonomy set the stage for a transformation in which consumers have very little choice about the health care they receive. Health care has become an investment opportunity where vast amounts of money have been siphoned away from service delivery into the pockets of executives and shareholders of megacorporations. The market solution has been a nonsolution to this point in that it has only succeeded in lowering costs without adequately addressing quality of service or the distribution and allocation of services.

The ethical physician is inevitably in tension with a system designed to limit or deny the care given to his or her patients. While recognizing that resources are finite, the ethical physician must struggle to do the best possible for individual patients without compromising integrity.

Novel Ethical Challenges in Twenty-First Century

Over the last couple of decades, we have witnessed a remarkable wave of information and communication technology advances that has fundamentally transformed the landscape of the field of medicine. In this new age of technology, it has become imperative that health care providers and administrators are equipped with the most up-to-date knowledge in this field to be able to deliver best possible care to the patients (Tang and Helmeste, 2000). As exciting as it is to have these novel digital, it is also vital to keep in mind that there is no substitute for prudent clinical judgment. While technology itself is neither ethical nor unethical, it is the intent and manner in which the technology is implemented that impacts the question of appropriate utilization. In many cases, lack of clear professional guidelines and legal regulations leads to concerning ethical issues (Fleming et al., 2009).

Telepsychiatry

Until recently, psychiatry has been a particular branch of medicine that did not rely heavily on high technology. However, the nature of psychiatry, which mainly utilizes audiovisual information lends itself particularly well to the practice of telemedicine. Second, in the last century, mental health services have undergone a major reform shifting away from institutionalized care to care in the community. This has produced a substantial strain on the system as the task of recruiting and retaining sufficient qualified providers has proved to be a challenge (Norman, 2006). Telepsychiatry has been viewed by many as the answer to this barrier to access and at present is important for countries with significant rural or dispersed populations such as Canada, Australia, and Russia (Tang and Helmeste, 2000). The cost effectiveness of telepsychiatry has been less clear. Some research shows that it can be less expensive for patients, reducing travel time, travel costs, and time off work. Other considerations, such as take-up rate and usage of the service, will factor into cost effectiveness as well. It is also important to keep in mind that the cost analysis equation of telepsychiatry is constantly changing with the varying cost of equipment and reliability of the technology (Norman, 2006). The ethical conundrum of telepsychiatry realizes the uniquely positive impact that it can have on patients, providers, and clinical outcomes, as well as the potential for harm and abuse that may ensue (Fleming et al., 2009).

Licensure and Credentialing Requirements: In the United States, there is a requirement that physicians hold a full, unrestricted license in all states in which they practice. An exception exists in most states, but not all, that allows physicians licensed in that state to consult with licensed physicians from other states and sometimes other countries. Parallel to the uncertainty surrounding licensure, there is also a question of whether a telepsychiatry consultant is required to be credentialed both at the base institution and at the remote site (Hyler and Gangure, 2004).

The question of licensure and credentialing requirements is often cited as a major barrier to the development of telemedicine networks and services, including telepsychiatry services. For many professionals, acquiring and maintaining multiple licenses is a significant professional and financial burden in complying with multiple state, region, or country regulations. Regardless, given that individual areas in the world differ in their definitions of practice, it is important that practitioners adhere to their area's regulations to ensure legally and ethically sound practice (Miller et al., 2005).

Informed Consent, Privacy, and Confidentiality: The principle of respect for patient autonomy dictates that physicians do their due diligence to facilitate the informed consent process by enhancing patients' understanding of their care and encouraging them to be active participants. As part of the informed consent process for telepsychiatry, patients should be advised on how their health information will be accessed, stored, transmitted, transferred, or protected. Given the novelty of telepsychiatry modality, a preliminary discussion with the patient regarding expectations concerning the sessions and treatment needs to take place before the consultation to establish a clear, explicit understanding of risks and benefits as well as shared responsibilities (Hyler and Gangure, 2004).

For centuries, Hippocratic Oath has tasked physicians to safeguard patients' privacy and confidentiality. This task has never seemed more daunting in this millennium as physicians' control over patient information has become diminished with the implementation of such practices as telepsychiatry and electronic medical/health record systems. Experts have warned that electronic transmission of patient information has increased the opportunity for infringement of the privacy and confidentiality of personal psychiatric information. In the case of telepsychiatry, this amplified threat for security breach is twofold: technological risks that originate from software of computer systems and risks directly posed by unauthorized

personnel (Hyler and Gangure, 2004). To address the first concern, risk management strategy would involve utilizing identity authentication (unique user IDs and passwords), secure networks with remote access controls, and encryption programs as well as adhering to the existing, regionally relevant legal and professional guidelines (Miller et al., 2005). The other unique privacy concern in telepsychiatry arises from possibility of outsiders to witness the session without being seen on the screen. This may range from presence of staff at the site of consultation or nonclinical technicians at the remote site of a technical service provider. Care must be taken to employ necessary precaution measures to protect against this type of potential security breaches as well (Hyler and Gangure, 2004; Norman, 2006).

Impact on Doctor–Patient Relationship: As health care technology permeates clinical practice more and more, we may be at risk of becoming technology centric rather than patient centric. Telehealth should function as an adjunct to, not a replacement of, the traditional physical encounter as many believe that physical proximity is still of paramount importance in securing the reciprocal connections integral to a healing and trusting relationship (Fleming et al., 2009). Given that telepsychiatry interactions are purely based on limited audiovisual cues of varying quality, physicians as clinicians no longer have the benefit of all their senses in uncovering and appreciating the richness and complexity of the patient (van Wynsberghe and Gastmans, 2009). Fundamental clinical cues such as eye contact, posture, facial expressions, body positioning, voice quality and tone, and hesitations, all of which can be relevant and pivotal in assessing the patient's emotional state, may be compromised or missed altogether due to limited audiovisual quality of telepsychiatry practice. Conversely, this setting can also limit the therapist to perform supportive gestures during videoconferencing sessions, which may be perceived as lack of empathy by the patient (Norman, 2006). This potential for depersonalization may present as a major barrier in relating to patients as whole persons and in turn has the potential to impede physicians' ability to provide the best care possible (van Wynsberghe and Gastmans, 2009).

Electronic Health Records

National electronic health record (EHR) initiatives are in progress in many countries around the world including Australia, Canada, Denmark, England, Estonia, France, Scotland, and the United States (Spriggs et al., 2012; Sutrop, 2011). Anticipated benefits from these nationwide initiatives include improvement in quality and continuity of care by improving efficiency, decreasing medical errors, reducing cost, reducing health disparities, improving the health of the public, and advancing education and research. Along with these benefits, there are also risks associated with the development, expansion, and maintenance of medical and health information in electronic form (Kopala and Mitchell, 2011). Ethical concerns surrounding informed consent, privacy, and confidentiality in EHRs are similar to those with telepsychiatry as discussed above. Some EHRs allow for the creation of sensitive notes that can only be viewed by certain groups of clinicians while others notify users when they are about to access sensitive information (Nielsen et al., 2013).

Proper Documentation and Data Accuracy: Clinical information pertaining to psychiatric care tends to contain more sensitive data than most other domains of medicine. Psychiatrists are encouraged to avoid unnecessary details and substitute general language as appropriate for specific details (Nielsen et al., 2013).

Despite the high hopes for EHRs to reduce medical errors, the very nature of EHRs raises concerns for the quality, accuracy, and reliability of data in the electronic records. Given the longitudinal and multiple-user nature of these records, they can contain extensive amounts of data that may not be current or relevant in a given clinical setting. Improper use of operational functions such as 'cut and paste' may result in an inaccurate representation of the patient's current condition and treatment. Worse, some EHRs employ autopopulate features that may introduce out-of-date, irrelevant, incomplete, or inaccurate information into the records. Concerns for incomplete data due to loss or destruction of data during data transfer have been noted as well (Kopala and Mitchell, 2011).

Communication and Collaboration: The doctor–patient relationship of present time differs greatly from past relationship when a physician was the sole provider of health care. Nowadays, a patient's health care is provided by multiple physicians of multiple specialties, usually in integrated delivery systems or at least coordinated in some way. Physicians today also share health care responsibilities with other nonphysician providers as well as support staff (Rothstein, 2010). One of the appeals of EHRs is the enhanced ease of information sharing across clinicians and service sectors. However, collaborative care requires clinicians to be mindful about effective communication that reflects a balance of restraint and release of information (Nielsen et al., 2013). Experts have called for different ways of disclosing health information only on a 'need-to-know' basis, limiting based on the role of the health care provider, date of the prior encounters, type of health care provided, diagnosis, or procedure (Rothstein, 2010). Authorization for release of information must specify what information will be disclosed, the purpose of the disclosure, the recipient of the information, and the date on which the consent expires. Some argue that reasonable effort must be made to limit the release of protected health information to the minimum necessary to fulfill the purpose of the request for information (Nielsen et al., 2013). The opponents of this stance warn that this approach may lead to making health care decisions based on incomplete information (Rothstein, 2010).

Social Networking/Media

With the emergence of social networking sites and media sharing sites over the last decade, such sites have become widely employed all over the world as a framework for self-expression as well as a means of communication. By enabling individuals and communities to gather, communicate, share, and collaborate, the benefits associated with these sites are numerous, ranging from rapid dissemination of useful information, increased interaction with friends and family, and development of new relationships, to facilitation of social and political change. However, they have also made it

increasingly challenging for physicians to keep their personal and professional lives separated. This is particularly relevant for the new generation of clinicians entering the health care field with ingrained communication habits, which are fundamentally different than their predecessors' (von Muhlen and Ohno-Machado, 2012). This paradigm shift has in turn created a unique set of ethical concerns.

Potential for Breaching Patient's Confidentiality: It is not unusual for users of social networking sites to employ this forum as a medium to vent about trials and tribulations of their everyday lives, including work-related issues. Physicians are no exception to this trend. Given this widespread practice, it is important to understand that one may still inadvertently reveal the identity of a patient without using any protected health information. A seemingly harmless anecdotal post about an interesting patient without personal identifying information may still be recognizable to a colleague with contextual knowledge about the case. Therefore, it is best not to post any information about patients on the social networking sites, no matter how deidentified it is (Ginory et al., 2012).

Some may argue that exceptions already exist where the public use of deidentified or disguised information about a patient is allowed. Such exceptions are generally granted for educational purposes such as presentation in scientific papers. Blatantly self-serving nature of posting information about patients as a status update is what distinguishes such unjustifiable uses from legitimate exceptions (Gabbard et al., 2011).

Potential for Publicizing Unprofessional Conduct: In addition to the aforementioned danger of breaching patients' privacy, other unprofessional conduct may involve postings including inappropriate language, negative comments about jobs or coworkers, derogatory comments about patients, depictions of substance use, and sexually suggestive/explicit material (Baer and Schwartz, 2011; Bosslet, 2011).

While physicians engaging in conduct unbecoming of their profession is not a new concern, physicians' unprofessional conduct in the digital era is accompanied by a novel set of implications. To begin with, the anonymity, albeit incorrectly perceived, and detachment from real-time social cues inherent in online forums can serve as the seductress for the users and lead them down the path of disinhibition to the level that may be atypical in real-life situations. Physicians are not immune to this temptation and may be more prone to lapses of professionalism in the setting of social networking (Baer and Schwartz, 2011).

One crucial point to note about the social networking sites, whose very nature relies on dissemination of information through 'second-degree' friends, is that it facilitates the spread of information faster than any other media. Therefore, online information available through social networking sites is not only easily accessible and widely available but also very durable. Once any unprofessional conduct has been displayed in cyberspace, it is very difficult, if not impossible, to erase the digital footprint. Even if one deletes the original unfavorable post, it will continue to exist in cyberspace unless everyone with whom it has been shared delete it as well (Bosslet, 2011). It is also imperative to note that questionable online content, be they words, pictures, or videos, has the potential not only to reach an unintended audience but also to be taken out of context (Baer and Schwartz, 2011).

Since public display of physician's lack of common sense and sensibility can be potentially detrimental to personal integrity, relationships with patients and colleagues, and employment prospects, physicians should be mindful that traditional expectations regarding the conduct of the medical profession still apply in this nontraditional context. In the face of this newly emerging pitfall, physicians should be vigilant about privacy settings on social networking sites and educate themselves about the potential effects of technological and information-sharing advances on professionalism (Baer and Schwartz, 2011).

Potential for Boundary Transgressions: 'Friend requests' on social networking sites bring yet another challenge to maintaining a proper boundary in doctor–patient relationship. Physicians may worry about the potential negative impact on the therapeutic alliance, if they were to decline a friend request from a patient. On the other hand, if it were to be accepted, each party would be allowed full access to the other's profile, which would most likely be more revealing than what is generally disclosed in a treatment relationship, especially from the physician's side. Depending on the type of information revealed, this may result in a boundary crossing or worse, a boundary violation (Gabbard et al., 2011; Ginory et al., 2012). In some parallel way, a friend request may be conceptualized as a gift offer from a patient to a therapist, where conscious and unconscious motivations and expectations associated with the gift should be further explored (Ginory et al., 2012).

Before becoming 'friends' with the patient on a social networking site, the physician must ask himself or herself how an online connection would be directly related to patient care. Given the concern for forming dual relationships, which in most cases do not have a therapeutic value and in some cases can be straight up harmful to the patient, the physician should always strive to establish and maintain appropriate boundaries (Ginory et al., 2012).

Safeguard Measures

Technological advances in the health care field have been adopted at different paces in different areas of the world, based on existing infrastructure and resources. Physicians should keep abreast with their regional, governmental, and institutional guidelines to ensure that proper administrative, physical, and technical safeguards are employed in their practice when using these digital tools for patient care. When indicated in cases of electronic medical records, appropriate deidentification methods should be utilized to assure patients' privacy and confidentiality. In the event that a security breach occurs involving personal identifiable information, specific steps must be taken to address the incident and mitigate potential harmful effects. Technical expertise should be sought to guarantee the use of these digital tools in a productive and safe manner. As with any traditional clinical encounter, helping patients understand the procedures and policies governing the care, custody, control, and disclosure of their health information using these new digital interfaces, as well as risks and benefits associated, is a crucial part of the informed consent process

(Klein, 2011). When in doubt, physicians would do well to remember one of the cornerstones of professionalism, respect for patient autonomy, from which springs obligations to ensure informed consent, privacy, and confidentiality (Fleming et al., 2009).

Conclusion

Looking back to the longstanding traditions of medical ethics, we are now in a position to better appreciate the place of the Hippocratic Oath in contemporary medicine. Though it is sometimes criticized for being anachronistic, its true value is apparent. The Hippocratic tradition in medicine provides a perspective of enduring values by which the shortcomings of modern economic expediency may be judged.

Abstract

In the twentieth century, moral philosophy and the theory of value came to be explicitly subdivided into two elements: metatheory, which concerns questions about meaning, justification, metaphysics, and psychology; and normative theory, which concerns more substantive questions about what is good, right, or valuable. In earlier centuries, these two kinds of question were seldom distinguished. More recently, dissatisfaction with any sharp separation of these areas of inquiry has grown: how are we to judge the adequacy of any account of meaning without asking whether it does some justice to widespread substantive convictions? The distinction nonetheless will make the presentation below more manageable. The focus of this article will almost exclusively be on the so-called 'analytic,' Anglo-American philosophy and its claimed antecedents, although fundamental work on ethics and the theory of value has of course been done in other traditions.

Ethics

Metaethics

There is no agreed-upon distinction between the terms 'ethics' and 'morality,' and they are used in philosophy more or less interchangeably (although Williams, 1985 associates 'morality' especially with duty-based systems). Both terms show, in their origin, a relation to social customs – 'ethos' and 'mores' – and both have a descriptive as well as a normative sense. In the former sense, we can ask "What was the Greek warrior's ethic?" or "How has morality evolved in Western Europe over the past two hundred years?" In the latter sense, we can ask "What is the ethical thing to do when one accidentally learns of a deep confidence?" or "Is it moral for us to carry out animal experimentation?" (*see* Conventions and Norms: Philosophical Aspects).

The descriptive aspect seems fairly straightforward, at least once one has noticed that there are wider and narrower uses (see Gibbard, 1990). In the wide sense, a system of morality is virtually any code of conduct that concerns how to live, regardless of its particular content or social import; a warrior ethic might favor unstinting cruelty toward one's enemies; a personal morality might glorify selfishness or esthetic accomplishment over everything else, even if society finds this abhorrent. In the narrow sense, morality is taken to involve norms of conduct with a distinctive purport, sometimes characterized in terms of a moral point of view, as contrasted with, say, an esthetic or prudential point of view (see Baier, 1958). Morality, narrowly understood, is said to involve some or all of: impartiality, concern for the well-being of others, treating like cases alike, willingness to cooperate, a notion of personal agency and responsibility, associated feelings of impersonal anger, guilt, or deservingness. In the wide sense, we can ask of virtually anyone or any society, "What is his (or their) morality?"; in the narrow sense, we can ask, "Does this individual (or this society) have a morality, and, if so, when did it emerge?" Much of the interest of philosophers and social scientists in individual moral development or in the historical development of morality concerns morality in the narrow sense. There is an active debate over whether various ancient civilizations recognized morality, as distinct from enlightened prudence or religious requirement (see Annas, 1993). Some social psychologists have suggested that there are three main types of morality: an ethic of autonomy, dominant in the West, based primarily on concepts like those of individual freedom, rights, fairness, justice; an ethic of community, prominent in much of East Asia, based primarily on concepts like those of duty, loyalty, hierarchy, interdependence; and an ethic of divinity, well-elaborated in India, based primarily on concepts like those of sanctity, the natural or sacred order, sin, pollution (Shweder et al., 1997; see also Fiske, 1991; Rozin et al., 1999).

An important moment came when Prichard (1912) convinced virtually everyone that showing certain principles of conduct to be advantageous would not suffice to show they had distinctively moral standing. Recent interest in the possible evolutionary origins of morality also typically concerns morality in the narrow sense: 'debunking' views tend to emphasize that the gene- and kin-oriented mechanisms of natural selection are not impartial; 'vindicating' views tend to emphasize that these mechanisms could have equipped us with psychological resources – empathy, cooperativeness, concern for fairness – that can be mobilized culturally on behalf of genuinely moral practices (e.g., see Thompson, 1995; Katz, 2000). Some debunking views argue that the fact that evolutionary forces have tremendously influenced the contents of our moral judgments and evaluative attitudes gives us reason to deny that there are moral or normative truths that hold independently of the evaluative attitudes of the agents to whom they apply (see Joyce, 2006; Kitcher, 2006; Street, 2006). Research into the neural bases for our moral intuitions has led some to discount the trustworthiness of certain of these intuitions (see Greene, 2003; Singer, 2005). 'Experimental philosophers' have used scenario-based survey instruments to raise similar questions and to challenge philosophers' grasp of 'common-sense morality' (Knobe and Nichols, 2008). The normative import of these arguments, however, is strongly debated (see Copp, 2008; Berker, 2009; Enoch, 2010).

Philosophical analysis of moral language in the normative sense also has focused on the narrow use of the term, although this has not eliminated controversy. Central to the disputes has

been the questions of whether the primary semantic function of moral sentences is to describe or represent the world, the question of 'cognitivism.' A paradigmatic factual sentence like 'Alice is smoking' conventionally represents the world as being a certain way, as being such that Alice has the property of smoking. It distinguishes among ways the world might be. Cognitivists maintain that moral sentences like 'Smoking is wrong' conventionally perform the same function. Noncognitivists disagree. They maintain that moral sentences conventionally distinguish among ways moral systems might be. Expressivists contend that the nature of moral beliefs is, in the first instance, to be explained in terms of their psychological properties – say, as states of norm-acceptance or planning states – rather than in terms of their intentional properties as states that represent the world as being a certain way. They maintain that the primary semantic function of moral sentences is to express desire-like attitudes or commands intended to influence behavior (see Ayer, 1936; Stevenson, 1937, 1944; Hare, 1952; Blackburn, 1984, 1998; Gibbard, 1990, 2003; Schroeder, 2008), although some expressivists allow that moral sentences conventionally express ordinary descriptive beliefs as well (see Schroeder, 2009 for an overview). Although many have been skeptical about whether expressivists can give an adequate compositional semantics for moral language (the 'Frege–Geach problem'), the influence of the expressivist strategy can be seen in areas outside metaethics; expressivist semantics have also been given for epistemic modals and adjectives like 'might' and 'probably,' for attitude verbs like 'knows,' for predicates of personal taste like 'tasty,' among others.

'Noncognitivism' is in some ways an unfortunate label, since moral discourse clearly involves a great deal of cognition and conceptual content, according to even those who claim its primary function is to express attitudes. For an attitude to count as distinctively moral, it must represent itself as responsive to certain features rather than others (those characterized by a moral point of view), and as regulative for certain emotions (e.g., guilt or resentment). Recently, so-called 'minimalist' theories of truth have gained currency, according to which the predicates 'true' or 'false' can appropriately be applied to sentences of a discourse so long as they enter seamlessly into familiar logical relations, patterns of inference, etc. (Horwich, 1990). Because moral sentences unquestionably do this – 'Stealing is wrong', unlike an imperative like 'Don't you dare steal!' can be the premise of a normal logical inference and embed under any expression that takes a clausal argument – there has been a tendency to concede on all sides of the debate that moral sentences can be said to be 'truth-apt' in the minimal sense. Contemporary noncognitivists also often accept that there are moral beliefs, properties, and facts. This might or might not suffice to earn the label 'realism' about moral properties (see Blackburn, 1993). If it does, some have worried that expressivists – or at least those who wish to endorse certain characteristic realist claims, given an expressivist interpretation – will not be able to distinguish themselves from traditional realists (see Gibbard, 2003; Dreier, 2004; Scanlon, 2003, 2009).

A burning issue is: even if utterances of moral sentences express beliefs, do moral judgments have an 'internal' or conceptual connection with motivation, such that making a moral judgment necessarily involves an element of endorsement not found in ordinary factual judgments? One can perfectly appropriately assert or believe that such-and-such rock is granite, for example, without expressing or having any favorable or unfavorable attitude toward that state of affairs. Similarly, if one cannot sincerely assert or believe that such-and-such situation is immoral while having no attitude of disapproval, then there remains a fundamental difference between a moral and a 'merely descriptive' discourse.

Defenders of such a difference must insist that this expressive function belongs either to the pragmatics of moral discourse or to its semantics. Expressivists and subjectivists pursue the latter path. Expressivists claim that utterances of moral sentences conventionally express motivational attitudes, and that in order to count as having a certain moral belief one must have certain emotional capacities and dispositions, general and particular. A simple subjectivism holds that utterances of moral sentences report rather than express that one (or one's society or group) approves or disapproves. Moral beliefs, on this view, are beliefs about one's attitudes or norms (or those of one's society or group). It may seem that expressivism and subjectivism result in a kind of moral relativism, according to which an individual's moral obligations essentially depend on what norms or principles she (or her society or group) accepts. However, expressivism and subjectivism, in the senses described above, are semantic positions about what moral sentences mean. As such, they are compatible with a variety of substantive theses about the universality of moral truths and the nature of moral properties. This is to their advantage; although relativist views have enjoyed a certain popularity, they typically account poorly for moral disagreement and often verge on incoherence, since they may include a nonrelativistic moral recommendation of tolerance in response to moral difference (but see Harman and Thomson, 1996 for a sophisticated debate on relativism).

Subjectivists about moral properties claim that moral properties are constituted in part in terms of psychological properties of agents. Contemporary subjectivists often take a sort of objectivist approach, thinking of moral properties neither as independent features of the world, nor as constituted wholly by psychological properties, but as a pairing of features of situations and characteristic (or ideal-typical) human responses to those features – rather in the way that dangerousness might be seen as a pairing of risk and fear – and, therefore, as response dependent (see Railton, 1986a, 1998a). Some theorists have been inspired in part by an analogy between moral properties and secondary qualities, such as color (McDowell, 1985). Color judgments show a high degree of objectivity and intersubjective agreement, so much so that they are often used in scientific observation and social coordination (e.g., 'red' for 'stop'). Yet, what it is to be a certain color may nonetheless essentially depend on kinds of subjective response, and those without a certain human-typical perceptual apparatus may be incapable of seeing color. Moral judgments might be similar. Those without a certain human-typical motivational apparatus might be incapable of moral experience, but since virtually all of us have (or could develop) these motivations, moral judgments can also be highly objective and intersubjective. In the moral case, the response – like fear – to the relevant

feature of the world would have a motivational aspect, perhaps arising from moral training in the virtues rather than sheer human physiology. For someone equipped with moral character, then, moral experience and judgment are necessarily accompanied by a motivating response. Does this sort of subjectivism lead to relativism – different patterns of moral training (say) yield different, yet locally apt, moral judgments? Not necessarily, since we can take our moral discourse, like our actual color discourse, to be anchored to our actual responses (by a semantic device known as 'rigidification'; see Railton, 1998b; Wiggins, 1998). The difficulty now is that those in different moral traditions may simply turn out not to have a common moral vocabulary with us.

Nonsubjectivists typically reject the conceptual or internal connection between moral judgment and motivation, and claim that moral judgments can be made without linguistic impropriety even by someone for whom they are normally motivationally inert. Such 'externalist' approaches recognize that in our ordinary life we presuppose certain typical motivations – so that it will be somewhat misleading to utter 'This situation is immoral' if one does not intend thereby to indicate or express any negative attitude toward it. Expressions of belief, and of moral evaluations, play certain roles in our social lives owing to various prevailing or presupposed background conditions, but these do not all become part of the conventional meaning of these words. We need not be driven to surprising conclusions like relativism or rigidification by the so-called 'motivation problem,' the problem of capturing the intimate connection between moral judgment and motivation. Externalists are divided into naturalists, who think the properties attributed in moral discourse are within the ambit of ordinary empirical knowledge, and nonnaturalists, who think of moral properties as in some sense irreducible or *sui generis*.

The first need is to explain how morality can be so controversial, if moral questions are in principle resolvable by matters of natural fact; the second need is to explain how moral properties can be known or referred to if they are not causally related to our experience, or if they are causally related to our experience, how irreducibly moral properties could be so related (see Scanlon, 2003, 2009; Huemer, 2005; Shafer-Landau, 2005; Parfit, 2006, 2011a; Wedgwood, 2007). Some naturalists outright identify moral concepts with certain naturalistic concepts; others give a broadly functional characterization of the role or meaning or moral terms – the truisms about morality and its social role – and leave conceptually 'open' the question of which particular acts, practices, and so on play the relevant role (for some varieties, see Brandt, 1979; Sturgeon, 1985; Railton, 1986b; Boyd, 1988; Brink, 1989; Lewis, 1989; Smith, 1994; Jackson and Pettit, 1996; Jackson, 1998; Schroeder, 2007). Of course, one possibility is that nothing can be found that will play all or most of the roles ascribed to moral properties, resulting in an error theory of moral discourse rather like atheism about religion (Mackie, 1977). Nonnaturalists argue that morality is not alone in showing the need to give an account of how we are able to talk about or have knowledge of nonempirical phenomena – mathematics poses similar problems (see Ross, 1930; Field, 1989; Wiggins, 1998; Enoch, 2010).

G.E. Moore, a nonnaturalist externalist, famously diagnosed a 'naturalistic fallacy' in moral philosophy, but the import of this claim has been widely misunderstood (Moore, 1903). He did not doubt, and few in the twentieth century have doubted, that moral properties supervene, in some sense, on natural properties – roughly, those properties accessible to empirical experience and investigation. It is, according to this view, a mistaken picture of value to think that two worlds could be identical in all empirical features yet different in their evaluative properties – e.g., one good and the other bad. In this sense, a kind of transition from 'is' to 'ought' is possible: given the way in which moral properties supervene on natural properties, we can learn whether acts are good or bad by learning of their empirical features. Moore's point is that moral concepts are conceptually distinct from the natural concepts or criteria that we might use to apply them – we do not contradict ourselves by asking whether happiness is good in itself, even if, as a matter of fact, it is (Frankena, 1939; Gibbard, 2003).

Oscar Wilde has Mrs Cheveley say, after being reprimanded by Gertrude Chiltern, "Do you know, Gertrude, I don't mind your talking morality a bit. Morality is simply the attitude we adopt toward people whom we personally dislike" (*An Ideal Husband*, Act II). Such a 'debunking' depends on a contrast between the normative purport of morality and the normative status it actually possesses or deserves. If '*x* is wrong' simply meant "I personally don't like *x*," there would be no presumption that it would be bothersome to be told that what one is doing is wrong. Morality might simply dress up personal dislikes in judgmental clothing. But giving an account of the meaning of moral terms – a metatheory – involves saying just what this dressing up consists of. (A collection of related essays and a more extensive survey is to be found in Darwall et al., 1997.)

Normative Ethics

It is difficult to imagine that what is right and wrong, good and bad, and the like have nothing to do with likes and dislikes, or broadly, with what matters to people or to sentient beings generally. Thus, there does appear to be something profoundly subjective about what is moral. Yet, ethics strives to develop objective forms of evaluation on this subjective base. We can see normative moral theories as seeking to develop a synthesis of subjective and objective elements that: (1) presents a credible account of moral rightness and value, one which fits reasonably well with our firmest moral judgments on reflection; (2) is psychologically and socially realistic ('ought implies can,' – a condition that is growing in importance in philosophy as we learn more about cognitive and motivational psychology and social dynamics); (3) involves no suspect metaphysical or epistemological assumptions (see Parfit, 1984, 2011a; Sinnott-Armstrong and Timmons, 1996; Campbell and Hunter, 2000; Huemer, 2005; Shafer-Landau, 2005; Wedgwood, 2007; Scanlon, 2009); and (4) enables us to locate a compelling basis for moral evaluation that would explain how those judgments could credibly be justified, criticized, and improved – since we are all aware of moral judgments that once seemed to many people obviously right or self-evident (such as the permissibility of slavery or the

moral irrelevance of animals), that we have subsequently come to reject. A normative moral theory should illuminate the underlying basis or rationale for the correct moral judgments (if such can be found), even if it calls for some normative rethinking on our part. This set of concerns is sometimes called seeking wide reflective equilibrium (Rawls, 1971; *see* Reflective Equilibrium).

We find three major living traditions in normative moral theory, one claiming as its spiritual ancestor Aristotle, the second David Hume, and the third Immanuel Kant.

On Aristotelian accounts, the fundamental question of ethics is "What is the good life?," and the answer is thought to take the form: the virtuous life (for some Aristotelian approaches, see Aristotle, 1989; Foot, 1978, 2001; MacIntyre, 1981; McDowell, 1985; Williams, 1985; Hursthouse, 1999). Virtues are robust traits of character, drawing on normal human faculties and motivations but shaped by proper moral training that enable an individual to see what is best or required, and act appropriately, in a wide range of circumstances. Virtue thus involves cognitive, affective, and conative elements. Moreover, virtues are thought to be mutually reinforcing ('the unity of the virtues'), and to yield a life that is itself good for the virtuous person to lead. Some have argued that virtue ethics presupposes a faulty picture of human psychology, and that situationism in social psychology shows that there are no character traits, hence no virtues that human beings could develop (Harman, 1999; Doris, 2002). But virtue ethicists have responded by engaging more with empirical psychology and emphasizing how robust and multitrack are the dispositions with which virtues are identified (Sreenivasan, 2002; Prinz, 2009; Annas, 2011). Typically, one cannot formulate strict principles of action that regulate the evaluations, deliberations, and actions of the virtuous agent: moral conduct essentially involves the exercise of judgment (shaped by the 'moral experience' of the virtuous agent), yet this need not preclude fairly objective recommendations about specific situations – much as we think that persons of sensitivity, discernment, and knowledge tend to converge in esthetic judgment even if esthetic evaluation cannot be captured in terms of strict rules. Although virtue theories take agents and their motives as the primary locus of moral evaluation, the view need not simply be individualistic. Aristotle, for example, thought the virtuous life to be possible only in the right sort of social and political setting, and only if one plays one's appropriate role in that setting (*see* Virtue Ethics).

Humean accounts, although they may allow for the possibility of virtue, typically do not assign it so fundamental a role. They seek to understand morality as fundamentally a scheme of social cooperation and regulation that enables individuals and groups to achieve sought-after ends that they could not attain individually, or on the strength of native instinct. In Hume's own view (see Hume, 1888, a related view is found in Smith, 1976), we are natively equipped with many of the sentiments necessary for such cooperation and regulation – empathy (what Hume called 'sympathy'), an intrinsic concern for kith and kin, a willingness to defer to custom, and so on – but others within this tradition (e.g., Bentham) suppose humans to be egoistic hedonists. Each strand solves the 'motivational problem' for morality in a distinctive way – Hume by the reshaping of native sentiment toward greater impartiality and willingness to cooperate through social conventions and 'artificial' in addition to 'natural' virtues, Bentham by the use of socially backed 'sanctions' for changing the incentives individuals face. Both of these strands recognize the need for a common, objective standard for moral assessment: 'the general interest.'

An influential form of this general approach is utilitarianism, which has taken a vast number of particular forms. Essential to it are two features: (1) a notion of a person's good or well-being that can be assessed prior to or independently of judging moral worthiness ('the good is prior to the right') – a theory of intrinsic nonmoral value (which need not be hedonistic, but could be perfectionist or involve the satisfaction of informed desires, personal or impersonal); and (2) a way of evaluating acts or practices across individual lives and over time by comparing tendencies to promote intrinsic nonmoral value, impartially assessed (which characteristically is thought of as maximizing, but need not be). Such value-based theories are often called consequentialist or teleological (goal-oriented or end-oriented; *see* Consequentialism Including Utilitarianism). Morality partakes of the subjective – it is essentially concerned with human interests and responses – because intrinsic goodness is grounded in what does, or could, matter to people (or to sentient beings generally) for its own sake. Yet morality is objective, because it seeks to ground distinctively moral judgments on an unbiased and impartial assessment of how acts and practices affect the long-term realization of intrinsic values in our lives.

On Kantian accounts, there is an attempt to locate a ground of rightness that is not in this way wholly dependent on such tendencies to promote nonmoral good. In some sense, the end does not entirely justify the means. Certain constraints on right action, prerogatives for individual choice, and duties to self and others, exist that are not functions solely of actual or expected consequences. Indeed, there is on Kantian views some resistance to the idea that we can characterize 'intrinsic nonmoral good': happiness derived from using another inappropriately as a means, for example, torturing an innocent, is not, they claim, a good at all. Normative theories that thus claim that the right is prior to the good – that facts about moral rightness ground, or are more fundamental than, facts about intrinsic value – are sometimes called deontological (duty based). Although Kant's own view is a bit hard to categorize at its foundation, views of Kantian inspiration have become the dominant and best developed form of philosophical deontology. (Other forms include Lockean natural rights theories, e.g., Nozick, 1974; *see* Libertarianism; and rational intuitionism, e.g., Ross, 1930. For a discussion, see Scheffler, 1994.) Humean moral theorists are able to give a rationale for encouraging non-consequentialist moral norms or motivations by a 'second-order' consequentialist argument: they are necessary to avoid individually or collectively self-defeating behavior (see Parfit, 1984; Railton, 1984). But how are we to give a rational justification of moral actions and duties, or constraints, prerogatives, and special obligations, if we are willing to fly directly in the face of consequences for what we most value? The Kantian approaches this question from the standpoint of a responsible agent asking "What have I reason to do?" (*see* Practical Reasoning (Philosophical Aspects)). From this standpoint, we recognize that desires and goals do not automatically give

reasons to act, since they are themselves up for scrutiny – and not merely because some are stronger or more basic than the others. Perhaps a desire for revenge, however powerful or however much a part of human nature, ought to be unequivocally fought, or rather weighed in an individual or social 'utility function.' We know from experience that we are free enough from the control even of 'natural' desires and interests to do this.

If one claims that one's act is rationally permitted, one in effect licenses the principle on which it is based as legitimate for anyone in similar circumstances. Like ideal legislators, we thus authorize ourselves to act by 'making law,' subjecting ourselves to the very same law even when we would prefer otherwise; the imperative is categorical. This universalizability condition on our wills brings an element of objectivity and generality to our decisions, based not on actual or expected consequences, but on a notion of ourselves as being autonomous (literally, 'self-law-giving'; *see* Autonomy, Philosophy of), seeking the moral law (see Kant, 1956; also *see* Kantian Ethics and Politics). Some contemporary Kantians prefer to understand this in terms of a hypothetical social contract: we show that our action is permitted or required by rules that we would all agree to (or find reasonable) in a situation of initial freedom and equality. Some acts or practices that would have good consequences – promoting social peace by treating individuals paternalistically in a secretive way, or permitting inequalities that raise total utility but do not tend to benefit all members of society – might thereby be ruled out (Rawls, 1971; Scanlon, 1998; for a related view, expressed in terms of the conditions for nondistorted social communication, see Habermas, 1990; also *see* Contractarianism). Other contemporaries inspired by the notion of autonomy have seen in this doctrine a radical affirmation of individual human freedom. Jean-Paul Sartre, for example, gave a distinctively existentialist account of 'choosing for all mankind,' holding that we can lapse into bad faith if we attempt to escape this absolute responsibility for our acts by pointing to things 'beyond our control,' such as 'regrettable circumstances,' 'natural urges,' or even 'moral principle' itself (Sartre, 1946).

One might see these three traditions as each emphasizing a different, yet important root of morality: the notion of the moral life as the best or fittest sort of life for humans (Aristotle); the notion of the moral life as one of benevolence and freedom from prejudice (Hume); and the notion of the moral life as one of respect for one's own freedom and rationality as well as that of others (Kant). Can all these elements be combined into one normative theory? No overarching synthesis has been found, and any view that seeks to be at all systematic cannot, so to speak, guarantee that it is optimal in three dimensions at once. Kant, aware there could be no guarantee, nonetheless took it to be an essential condition of the rationality of moral conduct that autonomous self-legislation would in the end yield both good consequences overall and a good life for humans – happiness and virtue would be united as the 'highest good,' if not in this life, then in the afterlife – but later Kantians have largely given up this doctrine of 'rational faith' and argued that Kant's account can stand even without postulating that these conditions are met. In his landmark *The Methods of Ethics*, Henry Sidgwick argued that "the intuitional method rigorously applied yields as its final result the doctrine of pure universalistic Hedonism" (1907: pp. 406–7). In a similar spirit, Derek Parfit has defended the provocative thesis that the best versions of Kantianism, consequentialism, and contractualism agree in their moral evaluations of all possible cases; they are "climbing the same mountain on different sides": the principles whose universal acceptance everyone could rationally will are identical to the principles whose universal acceptance would lead to the best results, which are identical to the principles no one could reasonably reject (Parfit, 2011a,b). This leaves open, among other things, the question of which normative factors are most fundamental. Even then, many are not convinced (see the commentaries in Parfit, 2011a).

An alternative response to this sense of multiple roots of morality is to claim that no systematic account of normative ethics should be attempted. Different circumstances, roles, personal histories, and so on make different sorts of moral consideration more or less appropriate, and this is an ineluctable fact of moral life. A relation with one's spouse or child is seldom best regulated by 'the general interest' or 'universalizable maxims,' a legislator cannot generally rely on personal virtue to tell her how to shape a complex piece of environmental law, and in our relations with animals we cannot regulate our conduct as if we were operating in a reciprocal realm of rationality. Experience, wisdom, and caring, not theory, enable us to act and deliberate well in a complex moral world (see Larmore, 1987). This view was given some impetus by, and finds continuing support in, a growing literature on moral development, where individuals who score highly on traditional tests of moral-theoretical sophistication may do poorly in practice in comparison with those capable of greater personal caring, empathy, and adaptiveness (see Gilligan, 1982; Damasio, 1993). Defenders of normative theory insist that systematic ambition is an essential antidote to arbitrariness or narrow-mindedness. Normative theories need not be understood as offering rule-like standards for acts or for moral reasoning; such theories must of course be combined with suitable motivation and sensitivity. Moral particularists (Dancy, 1993, 2004; Hooker and Little, 2000) and some feminists (see Card, 1991; Walker, 2007) counter that the systematizing impulse can itself become a form of moral insensitivity and arbitrariness. Disagreement remains concerning how best to understand the relation between normative theory and ethical reasoning and practice.

This is probably a healthy dialectic in normative ethics. It is important to emphasize, however, that resistance to normative moral theorizing need not be combined with a resistance to metaethical theorizing: moral particularism is often defended on the ground of an account of the meaning of moral concepts or on the ground of moral justification. Thus, on one influential view (Ross, 1930), morality consists of many mutually independent prima facie duties and permissions, the bearing of which in particular situations is not governed by general rules. Ross grounded his view in a nonnaturalist intuitionism in metaethics, and numerous contemporary defenses of Ross-like normative theories or other forms of particularism draw upon the idea that moral concepts are response dependent (see Dancy, 1993) or that fundamental values are plural and incommensurable (see Williams, 1981; Stocker, 1990; Chang, 1997; Thomson, 1997).

Theory of Value

In the first half of the twentieth century, theory of value (axiology) was a flourishing, central area of philosophy, represented by such major figures as G.E. Moore (1903), John Dewey (1929), C.I. Lewis (1962), and Ralph Barton Perry (1954). It has since gone so thoroughly out of style that it is difficult for a contemporary philosopher to recognize the themes or structure of a book like Perry's *Realms of Value*, with its chapters on *Motor-Affective Psychology*, *Gradation, Integration, and Mutation*, *The Science of Science*, and *The History of History*. This may partly be the result of a familiar tendency within disciplines to subdivide into specialities: ethics, esthetics, rational choice, law, and epistemology – all of these are domains of evaluation, yet they seldom are united together under a common rubric. Yet, like specialization generally, it involves some loss of perspective. The value-theoretic aspects of some subdisciplines within philosophy became, at least until fairly recently, relatively invisible (epistemology, for example) or radically de-emphasized ('philosophical aesthetics'). This has also given the mistaken impression that the so-called 'fact/value' distinction is disciplinary – ethics on the one side, science on the other. But value theorists would be quick to point out that values (but not simply moral values) as well as facts are fundamentally involved in all areas of human practice and inquiry.

There are excellent reasons for focusing on value as such. There is independent interest in investigating the nature and structure of value. Some questions about objectivity, cognitivism, and realism are familiar from metaethics, but other questions, such as the distinctions among the various forms of value (intrinsic, extrinsic, inherent, personal, impersonal, and so on), the possibility of commensurability or interpersonal comparison among values, and the relation of value to valuing attitudes or affect, merit sustained scrutiny. Fortunately, recent years have seen a growing revival of philosophical research into the nature of value (Anderson, 1993; Hurka, 1996; Railton, 1998b; Broome, 1999; Zimmerman, 2001; Rønnow-Rasmussen and Zimmerman, 2005; Rønnow-Rasmussen, 2011; *see* Value Pluralism).

Moreover, that moral philosophy in the twentieth century has been overwhelmingly preoccupied with questions of rightness and obligation (deontic or directive categories), rather than questions of value (axiological or evaluative categories), has given us a lopsided picture of morality and of the 'motivation problem' for ethics. Perhaps an 'ought' judgment – better, a 'must' judgment – expresses some motivation on the speaker's part. But judgments that a way of life would be valuable seem to highlight more the dependence of normative facts on the actual or potential motivation of those to whom they are applied. Further, evaluative judgments in general seem more directly responsive to facts of psychology, sociology, and history than are directive judgments (see Williams, 1985; Wiggins, 1998). The emphasis on deontic judgment has also tended to divorce philosophical ethics from value-involving subjects where duty plays a less conspicuous role. Kant and Hume, for example, saw quasi-esthetic evaluative judgment as at the foundation of morality.

Finally, a certain lost opportunity for philosophy for mutual enlightenment between 'analytic' and 'continental' philosophy occurred during the twentieth century. Moore (1903) observed that the philosopher whose outlook seemed closest to his own was Brentano (1902). Theorists within the phenomenological tradition in philosophy and psychology, such as Köhler (1938) and Heidegger (1962), explored our experience of value in life in ways quite comprehensible from the standpoint of, say, that of Dewey (*see* Phenomenology: Philosophical Aspects). Frankfurt School (see Habermas, 1990) criticisms of an overly narrow construal of value can be read alongside a growing body of Anglo-American literature critical of current notions of value in philosophy and economics, especially in rational choice theory and cost–benefit analysis (see MacLean, 1986; Anderson, 1993; also *see* Economics and Ethics).

This article is a revision of the previous edition article by R.J. Levine, volume 7, pp. 4788–4792, © 2001, Elsevier Ltd.

Abstract

In response to the atrocities committed by German medical researchers before and during World War II, the judges at the Nuremberg doctors' trial formulated the first set of international ethics guidelines for biomedical research on humans, the Nuremberg Code. Subsequently, numerous other guidelines have been developed and revised, beginning with the World Medical Association's Declaration of Helsinki and followed by the Council for International Organizations of Medical Sciences' International Ethical Guidelines for Biomedical Research Involving Human Subjects and the International Council on Harmonization's Guideline for Good Clinical Practice, to mention only the most influential. This article compares these four documents on how they protect participants in biomedical research.

Prior to World War II there were no international ethics guidelines for biomedical research involving human subjects. Since then, numerous sets of guidelines have been developed and promulgated, beginning with the Nuremberg Code (1947) and followed by the World Medical Association's (WMA) Declaration of Helsinki (1964, revised nine times, most recently in 2013), the International Ethical Guidelines for Biomedical Research Involving Human Subjects developed by the Council for International Organizations of Medical Sciences (CIOMS) in collaboration with the World Health Organization (WHO) (1982, revised in 1993 and 2002), and the International Council on Harmonization's (ICH) Guideline for Good Clinical Practice (1996), to mention only the most influential. These will be referred to respectively as 'Nuremberg,' 'DoH,' 'CIOMS,' and 'ICH.'

At the close of World War II, in Nuremberg, Germany, certain leaders of the Nazi regime were put on trial for having committed 'crimes against humanity.' During the course of one of these trials, the so-called doctors' trial, the first international statement of research ethics, the Nuremberg Code, was written. Subsequent international guidelines were designed to improve on or to interpret the efforts of their predecessors. WMA began its project in 1953 because it recognized a need for professional guidelines designed by physicians for physicians (as opposed to the Nuremberg Code, which was formed by jurists in a legal trial). The result of this project was the DoH, which was adopted at the World Medical Assembly in Helsinki, Finland in 1964. CIOMS introduced its Guidelines in 1982 by stating that they were designed to provide guidance for the correct application of the principles of the DoH, particularly when the research is initiated by researchers and sponsors in technologically developed countries and carried out in developing countries. Subsequent revisions of the CIOMS Guidelines in 1993 and 2002 departed from some of the DoH provisions and they are no longer considered simply as a commentary on the DoH. At the time of this writing, CIOMS Guidelines are once again being revised. Like CIOMS, ICH explicitly references the DoH:

> Good Clinical Practice (GCP) is an international ethical and scientific quality standard for designing, conducting, recording and reporting trials that involve the participation of human subjects. Compliance with this standard provides public assurance that the rights, safety and well-being of trial subjects are protected, consistent with the principles that have their origin in the Declaration of Helsinki, and that the clinical trial data are credible.
>
> Guideline E6: p. 1

These four documents vary considerably in length and scope. Nuremberg contains just 504 words in 10 paragraphs. The latest (2013) version of the DoH has 2240 words in 37 paragraphs. CIOMS 2002 is 65 pages long, consisting of a statement of general ethical principles, a preamble and 21 guidelines, each with an extensive commentary, plus a five-page list of items to be included in a research protocol. ICH is 53 pages long; however, it covers many other aspects of research besides ethics, the treatment of which is relatively brief. The titles or subtitles of the documents reflect differences in their scope. Nuremberg has no subtitle but the text makes clear that it applies to all types of experiments on humans. The original (1964) DoH was subtitled 'Recommendations Guiding Doctors in Clinical Research.' In the 1975 version 'clinical research' was changed to 'biomedical research involving human subjects.' In the 2000 and all subsequent versions, 'biomedical' was replaced by 'medical.' All three versions of the CIOMS Guidelines use the term 'biomedical research.' ICH focuses exclusively on clinical trials.

Ethical Universalism or Pluralism?

Discussions of international guidelines for research ethics generally reflect a tension between ethical universalism and cultural pluralism. Universalists hold that ethical principles are similar, if not identical, in all human societies and in all historical periods. It is as if ethical principles exist in human nature and are there to be discovered. The reason that they appear to change from time to time is that our ability to discern and understand them changes (one hopes for the better). The pluralistic position, by contrast, is that ethics are invented (not discovered) in the course of conversations conducted within particular societies; the results will necessarily reflect the histories and traditions of the cultures in which the conversations are conducted (Levine, 1996).

The authors of Nuremberg and the DoH attempted to create universal documents. ICH is addressed to the United States, European Union, and Japan but is referenced in many other countries. By contrast, CIOMS, which although it recognizes some ethical principles as 'transcendent,' also acknowledges the validity of some degree of cultural pluralism. The CIOMS writers aspire to 'global applicability' of a document that provides adequate ethical guidance for all known contemporary societies with the understanding that revisions will be required from time to time as ethics change in response to changing circumstances and understandings (Levine, 1996).

International statements of research ethics have no legal authority except to the extent that parts or all of them are incorporated in the laws of nations or other political entities having the authority to enact and enforce laws. This point notwithstanding, these documents have important moral status in that those who wish to criticize the ethics of various research activities generally rely on one or more of these documents to ground their judgments.

The Content of the Ethical Guidelines

Three ethical principles are widely recognized as basic or fundamental in the ethics of biomedical research and practice. These principles, which were first articulated in their most widely used form by the U.S. National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research (National Commission), are 'respect for persons,' 'beneficence,' and 'justice.' The first explicit reference to these principles in the international statements is in the 1993 version of the CIOMS Guidelines. However, the National Commission found in Nuremberg and the DoH implicit statements of respect for persons and beneficence (National Commission, 1978; Levine, 1988); concern for justice is also implied in the introduction to Nuremberg. Whether or not these principles are universally valid is the topic of a controversy beyond the scope of this article (Levine, 1996; Macklin, 1992).

The purpose of the ethical guidelines is to provide guidance on how research involving human subjects should be carried out so that it is responsive to the requirements of the basic ethical principles. Because they are considered relevant to virtually all fields of human behavior, the principles themselves are stated at such a level of abstraction that they do not provide clear direction on what behaviors are required or forbidden. Ethical norms (or rules) are incorporated in ethical guidelines to clarify what behaviors are prescribed or proscribed by the document. Ethical norms are either substantive or procedural. A substantive norm specifies behaviors that are required (or forbidden) because they are morally right (or wrong). Some procedural norms specify procedures that should be performed to determine the most appropriate behavior when the behavior has not been specified by a substantive norm. Other procedural norms are designed to provide documentary evidence that research has been conducted in accord with the relevant substantive norms (Levine, 1988).

An illustration. The principle of respect for persons requires that human persons must never be treated only as means to the ends of others. The substantive norm that requires informed consent is a specification of one way in which this principle is to be made operational in the conduct of research involving human subjects. The procedural norm that requires review and approval by a research ethics committee affords a method for determining what specific bits of information must be divulged to prospective subjects in a particular research protocol. Another procedural norm that requires the signing of a consent form provides documentary evidence that the behavior required by the substantive norm has been accomplished.

Ethical codes written by ethical universalists tend to have a high proportion of substantive norms. Those that espouse cultural pluralism tend to have a larger proportion of procedural norms. Substantive norms predominate in Nuremberg and the DoH while CIOMS and ICH contain a relatively large number of procedural norms along with abundant commentary on how the norms should be interpreted in various specific circumstances.

All of the substantive norms articulated in the leading international research ethics guidelines are variations on and elaborations of seven general normative statements (Levine, 1988). The first three of these are most closely related to the principle of beneficence which requires that those who perform research should maximize possible benefits and minimize possible harms and, further, that they should not deliberately injure any human being.

1. There should be good research design. This norm is linked inextricably to the purpose of doing research – to contribute to the development of generalizeable new knowledge. If the research is not designed adequately, there is little or no chance that it will make the desired contribution to the development of knowledge. As stated in CIOMS (2002: p. 23), "scientifically invalid research is unethical in that it exposes research subjects to risks without possible benefit."
2. There should be competent investigators. One purpose of this norm is identical to that of the first; competent investigators are much more likely than incompetents to succeed in producing beneficial new knowledge. In addition, there must be at least one member of the team of researchers who has the clinical competence to monitor the health of the subjects with a view toward prompt intervention as indicated to preserve the health of the subject by, for example, ending the individual's participation in the research or by administration of an antidote to some toxic substance. As stated in the DoH (paragraph 12): "Medical research involving human subjects must be conducted only by individuals with the appropriate ethics and scientific education, training and qualifications. Research on patients or healthy volunteers requires the supervision of a competent and appropriately qualified physician or other health care professional."
3. There should be a favorable (or reasonable) balance of risks and benefits. This is a judgment that must be made by the investigator and affirmed by the research ethics committee before the prospective subject is presented with an invitation to participate. The risks of interventions and procedures that hold out the prospect of direct benefit to the subject are justified much the same as they are in the conduct of medical practice – in terms of the anticipated benefit to the subject. The risks and benefits of interventions and

procedures that do not hold out the prospect of direct benefit for the individual subject (nonbeneficial procedures) must be justified in terms of the anticipated benefit to society. Nuremberg (Principle 6) requires that: "The degree of risk to be taken should never exceed that determined by the humanitarian importance of the problem to be solved." Plans to employ nonbeneficial procedures that present more than minimal risk in vulnerable populations require special justification. If in the course of conducting the research, the balance of risks and benefits ceases to be favorable, the investigator is required to intervene appropriately. Nuremberg requires: "During the course of the experiment the scientist … must be prepared to terminate the experiment … if he has probable cause to believe … that a continuation … is likely to result in injury, disability or death" (Principle 10). The DoH does not require separate analysis of the risks and benefits of individual components of research as described above. Rather, it calls for the evaluation of the entire research protocol as either beneficial or nonbeneficial: "Physicians who combine medical research with medical care should involve their patients in research only to the extent that this is justified by its potential preventive, diagnostic or therapeutic value and if the physician has good reason to believe that participation in the research study will not adversely affect the health of the patients who serve as research subjects" (paragraph 14).

The next two of the general substantive norms are most related to the principle of respect for persons:

4. There should be informed consent. The first principle of Nuremberg set forth the definition of informed consent that, with variations, has been incorporated in all subsequent guidelines and regulations:

> The voluntary consent of the human subject is absolutely essential. This means that the person involved should have legal capacity to give consent; should be so situated as to be able to exercise free power of choice, without the intervention of any element of force, fraud, deceit, duress, overreaching, or other ulterior form of constraint or coercion; and should have sufficient knowledge and comprehension of the elements of the subject matter involved as to enable him to make an understanding and enlightened decision. This latter element requires that before the acceptance of an affirmative decision by the experimental subject there should be made known to him the nature, duration, and purpose of the experiment; the method and means by which it is to be conducted; all inconveniences and hazards reasonably to be expected; and the effects upon his health or person which may possibly come from his participation in the experiment.

In this way, the prospective subject is invited to accept the researcher's goals as if they were his or her own at least for the duration of his or her participation. The result is that the subject is not treated as *merely* a means to the researcher's goals.

5. There should be respect for privacy and maintenance of confidentiality. 'Privacy' and 'confidentiality' are often incorrectly used as synonyms. 'Privacy' refers to the "freedom of the individual to pick and choose for himself the time and circumstances under which, and most importantly, the extent to which his attitudes, beliefs, behavior and opinions are to be shared with or withheld from others" (Kelman, 1977). 'Confidentiality' refers to a mode of management of private information; if a subject shares private information with (confides in) an investigator, the investigator is expected to refrain from sharing this information with others without the subject's authorization or some other justification. CIOMS requires that: "The investigator must establish secure safeguards of the confidentiality of subjects" research data. Subjects should be told the limits, legal or other, to the investigators' ability to safeguard confidentiality and the possible consequences of breaches of confidentiality (Guideline 18).

The final two general substantive norms are most closely related to the principle of justice which requires fairness in the distribution of both the burdens and benefits of research.

6. Selection of subjects should be equitable. From the 1940s through the mid-1980s, the prevailing attitude among commentators and policy makers in the field of research ethics was that participation in research was dangerous to the subjects and that researchers were inclined to exploit the socially and economically less powerful individuals who were most likely to serve as research subjects. For this reason, the ethical guidelines and regulations of that time focused on the protection of the prospective subject from bearing an unfair share of the burdens of research. The criterion for determining whether an individual (or a class of individuals) was in need of 'special protections' was 'vulnerability.' In the 1970s, vulnerability tended to be equated with 'limited capacity to give informed consent' and special procedural and substantive norms were developed to protect the rights and welfare of children, prisoners, the institutionalized mentally infirm, and fetuses (Levine, 1998). The category 'vulnerable' has been expanded subsequently to include others including "medical and nursing students, subordinate hospital and laboratory personnel, employees of pharmaceutical companies, and members of the armed forces or police" (CIOMS, 2002: p. 64), and patients with incurable diseases, persons in nursing homes, unemployed or impoverished persons, patients in emergency situations, ethnic minority groups, homeless persons, nomads, refugees, and those incapable of giving consent (ICH E6: p. 8).

Since the mid-1980s, research participation increasingly has been recognized as beneficial to both individuals and the class of persons they represent. This change began as a response to the AIDS activists who in 1986 pointed out that participation in a placebo-controlled clinical trial of AZT was not to be considered burdensome; it was, they argued, beneficial in that it was the only way people could have access to the only drug that anyone believed might be directed at the cause of their disease. Since then, ethical guidelines and regulations have begun to interpret the requirement for equitable selection of subjects as requiring also that vulnerable persons be assured of receiving a fair share of the benefits of participation in research. The 2013 DoH states: "Medical research with a vulnerable group is only justified if the research is responsive to the health needs or priorities of this group and the research cannot be

carried out in a non-vulnerable group. In addition, this group should stand to benefit from the knowledge, practices or interventions that result from the research" (paragraph 20).

7. There should be compensation for research-induced injury. CIOMS requires that "Research subjects who suffer physical injury as a result of their participation are entitled to free medical treatment for such injury and to such financial or other assistance as would compensate them equitably for any resultant impairment, disability or handicap" (2002: Guideline 19).

Exploitation of Subjects in Developing Countries

Industrial sponsors and investigators from technologically developed countries often conduct research designed to evaluate their therapeutic innovations in developing countries. Some commentators (e.g., Macklin, 2004) claim that this is done to lower the costs of the research and to take advantage of the less complex and sophisticated regulatory systems typical of developing countries. This is considered unjust in that these innovations, once proved safe and effective, are generally not available to the residents of developing countries owing to economic factors.

With the aim of preventing such exploitation CIOMS requires special justification for conducting research in developing countries (e.g., the research must be responsive to the health needs and priorities of the population or community in which it is to be carried out) and special obligations for the sponsors (e.g., they must engage in capacity-building in the host country to enable it to conduct independent ethical and scientific review). The 2002 version of these Guidelines requires that any product developed or knowledge generated in such research should be made "reasonably available for the benefit of that population or community" (Guideline 10).

The DoH requires that a new intervention must be "tested against those of the best current interventions(s), except in [limited] circumstances" (paragraph 33). This standard, which is similar to CIOMS Guideline 11 (although CIOMS uses the term 'established effective intervention'), is designed to prevent exploitation of all patients, including those residing in developing countries. However, some clinical trial experts argue that it may also have the undesired effect of obstructing the development for use in developing countries of inexpensive alternatives to expensive therapies employed in developed countries. The latter are generally the 'best current interventions.' An alternative which would not have this disadvantage is 'the highest attainable and sustainable' standard (Levine, 2000). 'Highest attainable' means that one should provide the best one can offer under the circumstances of the research rather than settle for the standard prevailing in the host country (often no therapy at all). The upper limit of what should be provided is defined by 'sustainability.' It would be unethical to develop a therapy that could not be made available to residents of the host country (sustained) after the research has been completed. Such research would not have been responsive to the health needs and priorities of the host country.

Informatics and Biobanking

Whereas the Nuremberg Code was written once and for all and therefore reflects the state of research at the time, the DoH and CIOMS have been revised periodically to take account of advances in research as well as other social, political, economic, and ethical developments. The ICH could likewise benefit from updating but the organization has given no indication that this will happen.

With the rapid growth of computing power from the 1970s onward, great advances have been made in medical informatics. The proliferation and increasing sophistication of databases and biobanks have enabled researchers in epidemiology, genetics and many other fields to work far more efficiently than before. At the same time these research tools have engendered new ethical issues and sharpened old ones such as privacy and confidentiality. Recent revisions of the DoH have incorporated some of these concerns while maintaining its status as primarily a statement of principles. The first paragraph of the 2000 and subsequent versions of the DoH specifies that medical research involving human subjects includes research on identifiable human material and data. A new paragraph in the 2008 version stated: "For medical research using identifiable human material or data, physicians must normally seek consent for the collection, analysis, storage and/or reuse. There may be situations where consent would be impossible or impractical to obtain for such research or would pose a threat to the validity of the research. In such situations the research may be done only after consideration and approval of a research ethics committee" (paragraph 25). This paragraph was only slightly modified in the 2013 DoH.

CIOMS 2002 contain just one brief reference to health databases and biobanks, in the commentary on Guideline 18, 'Safeguarding Confidentiality,' the section on "Issues of Confidentiality in Genetics Research": "When biological samples are not fully anonymized and when it is anticipated that there may be valid clinical or research reasons for linking the results of genetic tests to research subjects, the investigator in seeking informed consent should assure prospective subjects that their identity will be protected by secure coding of their samples (encryption) and by restricted access to the database, and explain to them this process" (p. 77).

These very brief mentions of such important aspects of contemporary biomedical research are partly justifiable by the fact that CIOMS, WMA, and ICH have other documents that treat these subjects more fully: the CIOMS *International Ethical Guidelines on Epidemiological Studies* (1991, revised in 2009), the WMA's *Declaration on Ethical Considerations Regarding Health Databases* (2002), and ICH's *Choice of Control Group and Related Issues in Clinical Trials E10* (2000). The advantage of separate documents is that the subjects can be treated more fully than they could in the DoH, CIOMS, and ICH E6 Guidelines; the disadvantage is that they are not nearly as well known and therefore less influential.

Other Guidelines

Although the four documents described above are arguably the most important international statements on research

ethics, they are by no means the only ones. The following also deserve consideration, especially in countries where they have mandatory or recommended status:

- Council of Europe: Additional Protocol to the Convention on Human Rights and Biomedicine concerning Biomedical Research (2004),
- UNESCO: Universal Declaration on Bioethics and Human Rights (2005),
- WHO: Standards and Operational Guidance for Ethics Review of Health-Related Research with Human Participants (2011),
- UNAIDS/WHO: Ethical Considerations in Biomedical HIV Prevention Trials (2007, 2012),
- European Union: Regulation (EU) No 536/2014 of the European Parliament and of the Council of 16 April 2014 on Clinical Trials on Medicinal Products for Human Use, and Repealing Directive 2001/20/EC.

Abstract

The term ethnic cleansing emerged during the 1990s' wars of Yugoslav secession, but it has since been used to describe and theorize a range of ethnic conflicts, including forms of genocide and mass atrocity. Drawing on classical and modern historical cases, ethnic cleansing may include colonial or frontier cleansing of indigenous populations, forcible population transfers, and mass expulsions following partitions of postwar settlements, ideological 'classicides,' and elements of genocide. Theorizations have taken a number of analytical lenses, giving rise to issues such as democratic or wartime cleansing, humanitarian interventions and postconflict reconciliation, and ethnic cleansing involving resource or environmental conflicts.

From its original instantiation in the 1990s' wars of Yugoslav secession, scholars have extended the term ethnic cleansing to descriptively cover a wide range of empirical cases and to conceptually capture a distinctive category or type of ethnic conflict and nationalist violence. After outlining legal and scholarly definitions of ethnic cleansing, this article situates understandings of ethnic cleansing as a social phenomenon in wider historical contexts. It then examines some of the most influential theoretical perspectives or conceptual frameworks used to understand ethnic cleansing, and closes by considering these approaches in light of case studies and issues recently raised as the study of ethnic cleansing takes new directions.

Definitions and Properties

First popularly used in the 1990s during the Yugoslav wars (in Serbo-Croatian, *etničko čišćenje*, or, more precisely, *čišćenje terena*, cleansing the terrain), a key characteristic feature or property of ethnic cleansing – central to both legal and scholarly definitions – is that it involves the removal or mass expulsion of peoples from a territory. Based on the Yugoslav experience, in 1994 the United Nations Commission of Experts formally defined ethnic cleansing as a "rendering [of] an area ethnically homogenous by using force or intimidation to remove from a given area persons from another ethnic or religious group"; it is a "purposeful policy designed by one ethnic or religious group to remove by violent or terror-inspiring means the civilian population of another ethnic or religious group from certain geographic areas" (UN Commission of Experts Report, 1994: 33). Although legally recognized by the UN as a 'form of genocide,' it is nevertheless distinguishable from genocide both by intentionality and by a 'killing requirement': genocide requires the *intent* to destroy a group *as such* (often implying a quantitative threshold), while ethnic cleansing does not require proof of this intent but simply the removal (not necessarily killing) of a group from a territory. In international law, therefore, unlike genocide, ethnic cleansing does not formally require international intervention (Article II of the United Nations' Convention on the Prevention and Punishment of the Crime of Genocide includes the intent 'to destroy, in whole or in part, a national, ethnical, racial or religious group, as such').

Scholarly conceptualizations have similarly focused on the removal of a people from a territory by force or intimidation as the constitutive feature of ethnic cleansing. Sociologist Michael Mann (m: 11) defines 'murderous ethnic cleansing' as "the removal of members of one such [ethnic] group of another such group from a locality they define as their own," and a nation can be such a group when it claims collective political rights to a given territory. The historian Norman Naimark (2001: 3) problematizes the distinction between genocide and ethnic cleansing, arguing that ethnic cleansers intend "to remove a people and often all traces of them from a concrete territory…to get rid of the 'alien' nationality, ethnic, or religious group and to seize control of the territory they had formerly inhabited"; but whereas it is similar at one end to forced deportations, at the other it 'bleeds into genocide.'

Likewise, Gellately and Kiernan (2003: 19–20) conceptualize ethnic cleansing as only partially distinct from either ethnic conflict or genocide: because it involves the "'purification' of a territory, not necessarily of a population," the (non) violent deportation of an ethnic group from the territory can precede and/or accompany genocide, making it a separate and distinguishable event. Political scientist Brendan O'Leary et al. (2001: 32) conceives of "ethnic expulsion as a right-peopling strategy," distinct from those strategies that move borders: it is "the intended, direct or indirect, forcible movement by state officials, or sanctioned paramilitaries, of the whole or part of a community from its current homeland, usually beyond the sovereign border of a state." Geographers Toal and Dahlman (2011: 5) define it more sharply as a territorializing military tactic, "as much about seizing and consolidating territory as it is about identity…[it] involves the ethnicization of space," whereby a "landscape is wiped clean and available for re-inscription as an ethnically homogeneous homeland."

Importantly, then, ethnic cleansing has been most commonly placed on both empirical and conceptual continua of practices of organized or unsystematic violence. Although there is no precise international crime under the term 'ethnic cleansing,' it is deemed 'contrary to international law,' and its practices or instrumentalities – forcible deportation, torture, arbitrary detention, rape and sexual assault, or extra-judicial executions – are considered war crimes, crimes against humanity, or otherwise fall under the terms of the Genocide Convention (UN Commission of Experts Report, 1994: Part III,

Section B). Moreover, these practices have been extended beyond simply the physical removal of a people, to also include the removal or erasure of evidence of cultural identities and practices. So ethnic cleansing commonly involves the destruction or desecration of religious symbols and buildings, cultural artifacts, and other traces of a groups' cultural existence. While ethnic cleansing can legally blur into – or become a subset of – genocide, for most scholars and legal experts it still retains valuable empirical elasticity and theoretical utility for analyzing a range of historical and contemporary practices that do not, by themselves, constitute genocide (see Blecher, 2005; Hayden, 1996) (*see* Ethnic Conflicts).

Ethnic Cleansing in Historical Contexts

Since the early 1990s, therefore, scholarly work across the social sciences has sought to stretch ethnic cleansing's empirical elasticity by extending its conceptual insights to a wide range of practices, and to an even wider variety of historical and contemporary contexts. The broadest and most influential organizing historical framework for understanding ethnic cleansing problematizes its essential 'modernity.' A number of scholars view ethnic cleansing as an empirically modern phenomenon entwined with key sociopolitical and ideological processes associated with modernity, such as the construction of citizenship, nationalism, democratization, or the institutional rise of the nation state (see, among others, Mann 2005; O'Leary et al., 2001; Naimark, 2001; Bauman, 1989). Yet other scholars locate instances of ethnic cleansing in antiquity or in pre-modern contexts, especially the ancient empires (see, for instance, Kiernan, 2007; Bell-Fialkoff, 1996).

These latter scholars argue that the practices of removing, killing, or expelling peoples in premodern historical contexts invoked religious, political, or other ideologies, and that they effectively possessed the essential features of modern ethnic cleansing, albeit recognizing that its force and systematic intensity have increased with the political capacities of the modern state. The most commonly cited examples of the cleansing of 'undesirable populations' are the atrocities, displacements, and massacres that characterized Babylonian, Greek, and Assyrian societies (compare dissenting discussions, Kiernan, 2007: Ch. 1; Mann, 2005: Ch. 2). Kiernan (2007), for instance, argues that 'cults of antiquity' and animosities toward non-agriculturalists characterized classical massacres; and Bell-Fialkoff (1996) suggests that over the course of 3000 years, cleansing was variously used to maintain control over populations, including religious minorities in early modern history. Moreover, Goody (2002) argues that religion was often the basis of cultural identifications and ascriptions in the early stages of the formation of modern nation-states, underscoring its centrality to 'cleansing.'

Ethnic cleansing 'modernists,' by contrast, argue that the core constitutive property of ethnic cleansing is its drive to homogenize territories, something historically located in the modern nationalist political claim to be ruled by co-ethnics, in a modern notion of 'we the people,' and in the ideologies and instruments associated with the rise of the modern state (*see* War and Nationalism; War and Democracy; Nation-State and War). While these scholars work from different epistemological perspectives, a belief in ethnic cleansing's essentially modern imperative is shared: Mann (2005), for instance, argues that it is the 'dark side of democracy,' Hinton (2002: Ch. 1) that it is the 'dark side of modernity,' and for Bauman (1989), the Holocaust itself was constitutively implicated in modernity. On this view, the cluster of underlying sociopolitical forces relevant to understanding ethnic cleansing – most especially democracy, welfare states, and citizenship – are organized around ethnic or national criteria of inclusion and exclusion, so ethnic cleansing is characterized by its political exclusivism.

The distinction within this organizing historical framework between 'modernists' and 'pre-modernists,' therefore, often turns less on evaluations of ethnic cleansing's practices, tactics, or instrumentalities than it does on assessments of the modernity of its ideological justifications and commitments – including whether or not group ascriptions are viewed as 'primordial' or as cultural constructs of political modernity.

Yet whether seen as premodern or modern, a loose typology of historical cases of ethnic cleansing has emerged in the scholarly literature. One such set of cases involves 'frontier ethnic cleansing,' or those colonial policies and settler practices that have historically targeted indigenous populations (cf Kiernan, 2007: Part II; Mann, 2005: Ch. 4; Anderson, 2005; Hinton, 2002: Part I). Tsarist Russia's settler policies between 1855 and 1866 toward groups in its Caucasian borderlands involved the colonial cleansing of between 500 000–900 000 Muslims, who experienced pressured and coerced emigration as a result of Tsarist land, settlement, and agricultural policies (Breyfogle, 2003). Similarly, US President Andrew Jackson's Indian Removal Act of 1830 and the forcible relocation and removal of Cherokee, Choctaw, Seminole, and other Native American nations, known as the Trail of Tears, has been considered a form of ethnic cleansing (Carson, 2008; Kiernan, 2007: Ch. 8). The related conquest of Texas in the nineteenth century involved a kind of ethnic frontier warfare, whereby settlers challenged native populations for hunting lands and ultimately 'cleansed' them from their territories (Anderson, 2005). German colonists' killing of an estimated 80% of Namibia's Herero population in German South West Africa between 1904 and 1908 (by some accounts prefiguring Nazi ideological commitments) is also considered frontier or colonial ethnic cleansing (Sarkin, 2011; Madley, 2004). These historical cases of ethnic cleansing – sometimes blurring into the genocide or the 'ethnocide' of particular indigenous populations – are constituted less by specific practices or tactics of 'cleansing,' and more by its ideological or colonialist underpinnings, whether civilizational, expansionary, or settler.

A related set of cases links postcolonial instances of ethnic cleansing to specific colonial identity regimes or to the aftereffects of colonial practices of local rule and social control. Mamdani's (2001) study of Rwanda, for example, argues that the logic of the 1994 killings in Rwanda (and earlier cycles of Hutu/Tutsi killings and reprisals) can only be understood against the historical context of Belgian and British colonial racializations of social ascriptions and hierarchies. And although the character and impact of the Belgian colonial state's identity regimes in neighboring Burundi differed from those of Rwanda, they similarly reshaped Tutsi and Hutu relations administratively, ascriptively, and in terms of landholding (Uvin, 2002; Lemarchand, 1994: Ch. 3).

Another set of historical cases that have been characterized as ethnic cleansing are those that involved mass expulsion or forcible population transfers, most often associated with the dissolution of empires and the creation of nation-states in East Central Europe and the 'demographic engineering' that these processes entailed. Ther and Siljak (2001: 1–2), for instance, conceptualize this form of ethnic cleansing as sanctioned or nonsanctioned "repressive actions" that involve the "involuntary transfer of entire ethnic groups from one country to another," especially deportations (the coercive transfer of minorities to other regions within a country) and expulsions (the forced removal of minorities from a country). To make the newly drawn political boundaries coincide with ethnolinguistic boundaries, between 1944 and 1948, 31 million people – Germans, Romanians, Bulgarians, Poles, Ukrainians, Czechs, Slovaks, Greeks, Serbs, Croats, and Macedonians among others – were forcibly transferred or expelled in internationally sanctioned treaties or by nonsanctioned resettlement policies (cf Hayden, 1996; Ther and Siljak, 2001; Várdy and Tooley, 2003: Part II; Snyder, 2003). In this context, the forcible resettlement of ethnic Germans from Czechoslovakia is sometimes referred to as 'liberal ethnic cleansing' because it was sanctioned by treaty at Potsdam in 1945.

But these population transfers had been preceded by the purposeful expulsion of other minorities in East Central Europe, Russia, the Balkans, and the territories of the Ottoman Empire, during and after the Balkan Wars of 1912–13 and during and after WWI, to consolidate demographic claims to territories: two million people were forcibly expelled or deported by the 1923 Treaty of Lausanne in sanctioned population exchanges that redefined the borders of the states of Turkey, Greece, and Bulgaria that emerged from the Ottoman Empire (see the contributions in the 2008 Special Issue of the *Journal of Genocide Research* 10(1)). These internationally sanctioned population exchanges formalized expulsions and sanctioned certain property claims. In Tsarist Russia during WWI, the army forcibly deported approximately 800 000 Jewish and German minorities away from the war front in what were considered 'ethnic expulsions' (Lohr, 2003). Most famously, in 1915, millions died as the Ottoman Empire deported its entire Armenian population from the northeast frontier in what moved beyond ethnic cleansing to genocide.

This set of historical cases in particular highlights certain definitional issues: just as the continuum between ethnic violence at one end and genocide at the other is typically taken to contain ethnic cleansing within it, so too the issue arises as to when fear- or intimidation-induced emigration becomes forced migration or coercive displacement and transfer, and, relatedly, whether legally sanctioned population transfers or exchanges should be similarly considered forced relocation or 'repatriation.' The consensus on this has shifted, as the practices of ethnic cleansing have been enveloped within a human rights framework in the post-WWII period (see discussion below). So while in the early- and mid-twentieth century, international efforts considered legally sanctioned population movements to be viable alternatives to minority rights or protections, today they are generally viewed as unacceptable 'liberal' forms of cleansing.

A related set of historical cases further underscores the difficulty in capturing what, precisely, is considered ethnic cleansing. Some scholars view violent state-directed or spontaneous large-scale population movements and massacres occasioned by state partitions to be instances of ethnic cleansing. The partition of Pakistan and India in 1947, for instance, and the resulting large-scale massacres that occurred in the Punjab were, like those in Rwanda, cycles of retribution – not state sponsored, but not unorganized either: between 200 000–360 000 Hindus and Muslims were killed as up to 12 million crossed the new borders of the partition (Brass, 2003; Hansen, 2003).

Finally, a distinct kind of ethnic cleansing involves what Mann (2005) terms 'classicide,' or mass expulsions, killings, and deportations whose targets are class or political enemies, and which may or may not be culturally marked. Such cases include the Soviet era deportations of Chechen-Ingush and Crimean Tatars (Naimark, 2001: Ch. 3), the class enemy-based murderous ethnic cleansing in Cambodia (see Mann's 2005: Ch. 11 account), or Stalin era ethnic deportations (Martin, 1998). In the context of Soviet ethnic deportations (including ethnically based agricultural resettlement), Martin (1998), for instance, argues that ethnic cleansing occupies a middle position between genocide and nonviolent pressured ethnic emigration – in this case occasioned not by Russian nationalism, but by Soviet xenophobia. These cases of classicide also blur into a set of cases considered 'politicide': recent Ethiopian law has defined the forcible removal of political groups in the country as ethnic cleansing, and the extension of this kind of legislation to other countries is expected (Tiba, 2007). Naimark (2011), too, argues that the politically defined killing and forcible resettlement of kulaks and Ukrainian peasants under Stalin also constituted forms of ethnic cleansing/genocide; and Gratz (2011) argues that the specific targeting of political, religious, and cultural elites in the violence in Bosnia similarly constituted ethnic cleansing as 'eliticide.'

Theorizing Ethnic Cleansing

These various historicizations have given rise to several overlapping explanatory or analytical frameworks for theorizing ethnic cleansing. Individual scholars often draw on one or more of these theoretical frameworks. The most common analytical framework examines ethnic cleansing through ethnic, nationalist, cultural, or other identity lenses. Seen as one potential result of the political claim to be ruled by co-ethnics, for instance, Mann's (2005) influential explanatory framework situates murderous ethnic cleansing along a continuum of violent or nonviolent practices or policies; these policies are also arrayed along a separate axis that involves the elimination, accommodation, or containment of cultural difference. While sometimes treating the relevant social groups as essentialized or reified categories, Mann's case studies (Yugoslavia, Armenia, the Nazi Holocaust, Cambodia, Rwanda) suggest that the intent to cleanse, and the degrees of violence associated with it, are variously dependent on state factionalization (often precipitated by war), ethnonationalist 'core constituencies,' and the intersectionality of ethnic differences with other social distinctions, most notably class or region. His analytical schema ranges, therefore, from nonviolent multiculturalism, to pogroms, to violent displacement, to genocide (subsuming ethnic cleansing). So 'murderous ethnic

cleansing' can involve not only forced displacement, but also biological sterilization and genocide. O'Leary's et al. (2001) explanatory framework likewise situates ethnic cleansing (e.g., expulsion and genocide) as a strategy for *eliminating difference*, distinguishing it from those strategies used for *managing difference* (e.g., arbitration or consociation). Hinton (2002) conceptualizes ethnic cleansing (and genocide) as a process that essentializes identity differences – a defining dimension of modernity – and then seeks to erase these differences through a homogenizing nationalism.

A key feature of these theoretical contributions is that ethnic cleansing is moored around nationalism or culture, and the key issue is how and why cultural differences are eliminated, controlled, or displaced from a given territory. Political frameworks – nation-state formation, the dissolutions of empires, democratization – are important processes whereby the cultural and the political or territorial are made congruent. So, for instance, modern ethnic cleansing is theorized as a form of organic or integral nationalism, which fuses the *demos* of democracy with the *ethnos* of nationalist homogeneity – and it centrally does so to control a given territory (Mann, 2005: 3–4). The idea of 'unmixing peoples,' and its associated forms of population transfer, similarly conceives of ethnic cleansing mainly through a nationalist or cultural lens (Blecher, 2005; Brubaker, 1995). Snyder's (2003: 197) conceptualization of Polish–Ukrainian ethnic cleansing in 1943, for example, as the "violent removal of populations in the pursuit of nationally pure space," conceptualizes the essence of ethnic cleansing as being primarily about cultural difference. These nationalism-based analytical frameworks, then, conceptualize ethnic cleansing as a cultural or identity problem of politics.

A second, related analytical axis for understanding ethnic cleansing focuses attention more specifically on distinctions in ethnic cleansing's motivating or organizing ideologies. The principle beliefs, rationales, and justifications given for the removal or killing of an outgroup can range from nationalist, religious, or sectarian beliefs, to racialist, secular political, and imperial or civilizational ideologies (cf Snyder, 2012; Kiernan, 2007; Straus, 2006; Mann, 2005; Lohr, 2003; Weitz, 2003). Viewed through the prism of its ideological commitments, these scholars explore the symbolic, political, or discursive language used, the intellectual origins of ideological underpinnings, the social carriers of those beliefs, and the self-ascribed beliefs of those involved in implementing or carrying out ethnic cleansing. In short, this theoretical framework seeks to retrieve the ideological or ideational underpinnings of those states, groups, and constituencies possessing, or involved in producing, organized exclusivist ideologies, and in particular it highlights the key social and political dynamics associated with 'othering': stigmatization, dehumanization, and racialization (Hagan and Rymond-Richmond, 2008).

A third explanatory framework for understanding ethnic cleansing seeks to better understand its perpetrators, its victims, and especially the critical role of the state and its various agents as instruments of ethnic cleansing. Here, careful consideration is given to those involved in the actual practices of ethnic cleansing: who are its proponents, instigators, or perpetrators? How involved are 'ordinary' citizens? How involved are organized societal groups such as paramilitaries, political elites, police, or armed gangs? Importantly, attention is given to explaining both individual-level motivations and the large-scale involvement of citizens (cf Straus, 2012; Mann, 2005; Mamdani, 2001; Staub, 1989). Scholars working within this broad conceptual framework examine not only the dynamics of reluctant or purposeful masses in the participation of ethnic cleansing, and in particular the use or deployment of norms of coercion (e.g., Bhavnani, 2006), but they also examine why some refuse to participate in ethnic cleansing or genocide (e.g., Dumitru and Johnson, 2011). Scholars also focus on explaining the violent dynamics and escalatory scale of ethnic cleansing, and the mediating macrolevel forces and microlevel motivations of individuals and midlevel 'constituencies' (Mann, 2005); on examining the relationships between leaders and followers, bystanders and aggressors, their social psychologies, the microdynamics of identity self-ascriptions and moral choices in the violent contexts of ethnic cleansing (Monroe, 2012; Snyder, 2010; Midlarsky, 2005); and on intentionality, and the relationship between beliefs and behaviors, particularly in contexts where killings are individualized, personal, or intimate (Straus, 2012, 2006; Verwimp, 2005; Waller, 2002). Straus' (2006) wider account of the ethnic cleansing/genocide in Rwanda, for example, focuses on the local dynamics of the killings in Rwanda by relying on in-depth interviews with imprisoned *génocidaires*; Dumitru and Johnson (2011) link macrotheories of ethnic war to microlevel explanations of ethnic killing by examining the underlying qualities of the ethnic relationships that deeply contextualize the ethnic cleansing in the first instance; whereas Uvin (1998) anchored an analysis around the salience and ubiquity of underlying structural violence in Rwandan society, something that generated a pervasive sense of fear, humiliation, and frustration – anticipating violence.

A fourth common organizing framework for theorizing or understanding ethnic cleansing is that of human rights, war crimes, and international law. Here scholars explore the entwined relationships among ethnic cleansing, genocide, and conceptions of human rights violations, crimes against humanity, and mass atrocity (Hagan and Rymond-Richmand, 2008; Hagan et al., 2006; Gellately and Kiernan, 2003; Hinton, 2002). Viewed within a human rights or international legal perspective, the empirical focus is often on assessing evidence or determining a set of practices that constitute breaches of human rights. The practices of ethnic cleansing, in other words, are the central focus, and they are read through the conceptual lens of international human rights law. So, for instance, unlawful detention, extrajudicial killings, rape and sexual assault, or targeted destruction of property are legal categories through which the tactics used for the mass rendering of an area ethnically homogenous, or to effect population displacement by intimidation or force, may involve laying siege to cities and indiscriminately shelling civilian populations, executing non-combatants, the use of concentration or detention camps of torture, execution, rape, and inhumane treatment, and razing villages to intimidate or uproot populations. This empirical overlap between the tactics or practices involved in genocide, ethnic cleansing, and war crimes or mass atrocity has also led to a re-framing of ethnic cleansing as a particular subset of human rights violations, that is, ethnic cleansing as a type of 'hard' human rights violation (Hagan and Rymond-Richmond, 2008; Hagan et al., 2006).

Comparisons, Cases, and Issues

While there are few analytically synthetic works on ethnic cleansing (cf Mann, 2005; Weitz, 2003), there are a number of comparative case studies organized around cases selected for historical, thematic, or geographical reasons (cf Snyder, 2012; Naimark, 2011, 2001; Carmichael, 2009; Gellately and Kiernan, 2003; Hinton, 2002). There are many more individual case studies that focus on either bounded instances of ethnic cleansing, or on mass killing and displacement amounting to some combination of ethnic cleansing and genocide. The most commonly explored cases are the violent dissolution of the former Yugoslavia, the Nazi Holocaust, Rwanda, East Timor, Cambodia, Guatemala, and Darfur among others (*see* Holocaust, The). Scholarly works on these most notable cases usually involve questions of how and why the ethnic violence occurred, what could have been done to prevent it, and what the policy 'lessons learned' might be.

But ethnic cleansing as both an empirical descriptor and as a conceptual construct is evolving, and more recent developments around the world are increasingly coming under scrutiny as instances of ethnic cleansing, in addition to revisiting historical instances of ethnic violence through more contemporary lenses, for instance. As a result, a number of analytical issues are emerging as suggestive not only of the development of new typologies of ethnic cleansing, but also of the directions that the history of ethnic cleansing is beginning to take.

1. The most cited feature of ethnic cleansing in the many individual case and comparative studies is its common occurrence under cover of war, civil conflict, or in the context of violent state partitions or secessions (*see* Civil Wars). In addition to some of the cases noted earlier, this includes recent studies of cycles of sectarian cleansings between Shi'a and Sunni in Iraq (Kenyon Lischer, 2008); the forced evictions of Tamil minorities in northwest Sri Lanka in 2008–09 following the end of a civil war; the ethnic cleansing characteristic of the conflicts in Africa's Great Lakes (Lemarchand, 2009); and the continuing coerced displacement of the Nuba in South Kordofan in southern Sudan in the wake of the secession of Southern Sudan in 2011. This is not new, of course; Mann (2005), Shaw (2007, 2003), Naimark (2001), Lohr (2003), Straus (2006), and Snyder (2012) among others have theorized along these lines with respect to earlier historical cases. However, as the empirical relationships among war, civil conflict, and ethnic cleansing are better understood, ethnic cleansing is increasingly theorized with less abstraction and greater local, empirical contextualization, embedding moments of ethnic cleansing within local politics – and pointing the way to the emergence of new empirical typologies around this type of ethnic cleansing (cf Kasara, 2010; de Waal, 2005a).
2. A related general consensus is that ethnic cleansing is often associated with processes of democratization: democratic legitimacy is used as a 'we the people,' exclusivist ideology (Mann, 2005); or ethnic elites play 'ethnic cards' for purposes of social mobilization, or more specifically because of the political stakes involved in the ethnic gerrymandering of electoral districts (e.g., Kasara, 2010; Malik, 2000). Kasara (2010), for instance, shows how arson attacks in particular neighborhoods in Nairobi and other cities in Kenya around the country's 2007 elections were forms of targeted ethnic cleansing, designed to segregate neighborhoods for electoral purposes. Similarly, the recent ethnic displacement and killing of Muslim Rohingyas in Buddhist majority Myanmar's current fragile and tenuous democratic liberalization involves pogroms and the burning of homes and villages along its western coast.
3. A third issue is the pervasiveness of rape and sexual assault in contexts of ethnic cleansing (Meger, 2011; Allen, 1996). Either spontaneous and unsystematic, or organized and systematic, rape, and in some cases forced sterilization, are usually theorized in the context of war more generally, or by conceptualizing women as the biological carriers of 'the nation,' and rape and sexual assault as the violent inscription of cultural identities on women's bodies (Mostov, 2000). A related issue receiving more recent attention is that of children born of ethnic cleansing rape and its related postethnic cleansing traumas (Carpenter, 2010) (*see* War, Political Violence, and Effects on Children).
4. Scholarly work on ethnic cleansing is also seeking more explicit policy prescription: how ethnic cleansing can be averted, or how and what kind of interventions can prevent escalation from lower levels of ethnic violence (Robinson, 2010; Mann, 2005: Ch. 17; O'Leary et al., 2005). Indeed, the 2005 UN World Summit Document (A/RES/60/1, 2009 UN Report) regarding the Responsibility to Protect (R2P) outlines states' responsibilities (and those of the international community) to protect populations against genocide, war crimes, ethnic cleansing, and their incitement. So Robinson (2010), for instance, shows how international armed intervention averted ethnic cleansing in East Timor in 1999; and O'Leary et al. (2005) argue that various forms of power-sharing or consociational arrangements can mitigate both the causes and effects of sectarian cleansing (*see* Conflict Mediation).
5. Another key issue highlighted in recent cases of ethnic cleansing has been its link to underlying resource and environmental conflicts – both those contexts characterized as resource-rich with tensions around the politicized extraction of resources, and those contexts that are resource-scarce (see especially the 2012 Special Issue of the *Journal of Peace Research* 49 (1)). Understanding ethnic cleansing in these contexts involves, for instance, exploring the roles of 'moral geographies' and the ethnically based claims to land of indigenous cultures. This is most notably examined in those conflicts along the African Sahel Belt, where resource-based ethnic cleansing occurs in contexts of stark poverty, fragile livelihoods, and vulnerable environments as it combines with ethnically marked access or control of social and political resources, and weak or infrastructurally fragile states. These have been highlighted as key factors underlying the ethnic cleansing Darfur and in the eastern Horn of Africa, for instance (de Waal, 2005b; Tubiana, 2007; UNEP, 2007). Locating an important element of Darfur's ethnic cleansing in the ways in which desertification and drought in Western Sudan placed severe environmental pressures on both pastoral and agricultural

livelihoods among Arab and non-Arab Darfuris, scholars point to the subsequent politicization of these underlying tensions, and link local and national politics to the independent effects of resource scarcity.

6. A sixth emergent issue in studies of ethnic cleansing may be broadly described as a cluster of related postethnic cleansing issues: reconstruction, return, and transitional, restorative, or postconflict justice and reconciliation. The practices of transitional and restorative justice, international and regional tribunals for reconciliation and accountability, and attention to the roles of memory and postconflict history teaching have all gained greater attention as focus turns to *postethnic cleansing* needs and realities (Straus and Waldorf, 2011; Hinton and O'Neill, 2009; Staub, 2006; Snyder and Vinjamuri, 2003/2004; Hinton, 2002: Part 4; Borneman, 2002; Minow, 1998). These include better understandings of ethnic displacement and refugee crises (cf Zetter, 2007; Peteet, 2005) and of postconflict environmental issues (e.g., UNEP, 2007). Moreover, following the Yugoslav conflicts, a 2005 UN resolution was adopted to accept the 'Pinhiero' Principles on Housing and Property Restitution for Refugees and Displaced Persons (outlined in UN Pinhiero Report, 2002–2005). It defined the rights and obligations of states toward those displaced by conflict, and specified that refugees and displaced populations, many occasioned by ethnic cleansing, have the specific rights to return to their pre-war homes (not just to their pre-war countries) or they are otherwise entitled to restitution of their homes and properties. This is also seen as a particularly important element in restorative justice and in building sustainable peace (Leckie and Huggins, 2011), and it has given rise to greater attention being paid to the modalities and possibilities for the reversal of ethnic cleansing, most exhaustively examined in the context of Bosnia-Herzegovina (Toal and Dahlman, 2011; Williams, 2005).
7. Another direction taken to better understand the modalities of ethnic cleansing is methodological: the methodologies involved in identifying ethnic cleansing (and genocide), measuring its social and environmental effects, and finding more sophisticated ways of assessing or quantifying its statistical parameters (deaths, disappearance, or displacement figures, for instance) are being extended to include the use of new technologies. In particular, this involves a greater diffusion of the use of satellite imagery/GIS to examine levels of housing and building destruction; overturned earth through infrared imagery to assess the existence of mass graves; and spatial geomodeling to determine incidents and locations of ethnic violence-related events, such as arson-induced displacement, road destruction to prevent population returns, burned crop fields, and the construction of detention centers or tent camps of the displaced (Hagan et al., 2006; Tabeau and Bijak, 2005). A contextualization of ethnic cleansing within a war crimes framework, combined with the adoption of these methodologies, has prompted sociologists, for instance, to critically re-assess ethnic cleansing as a 'complex humanitarian emergency'; this requires a better grasp of disease, health, and environmental effects, and innovative analytic techniques to better calculate mortality and displacement rates to take the full measure of the violence involved (e.g., Hagan et al., 2006). This scholarly work at once parallels and complements that recently undertaken by a number of human rights organizations and (inter) governmental agencies, such as the Harvard Humanitarian Initiative and the United Nation's 'Operation Satellite and Applications Program' (cf http://www.unitar.org/unosat/; http://hhi.harvard.edu/). These efforts embed the contemporary unfolding of ethnic cleansing (and genocide) into environmental and other humanitarian emergencies frameworks and link ethnic cleansing's methods and tactics to wider projects involving 'crisis mapping' through satellite imagery analysis (*see* Geographic Information Systems and Remote Sensing).
8. Finally, an important dimension in understanding the dynamics of ethnic cleansing has recently involved embedding it in geopolitical neighborhoods, border regions, and regional conflicts, with particular attention paid to the migration of the conflict through the large number of either cross-border refugees or internally displaced persons. This has given rise to a more sustained consideration of the workings of the short- and long-term volatile dynamics of displaced minorities in geopolitically vulnerable conflict neighborhoods and to how cycles of ethnic cleansing can occur. The displacement of Tutsis and Hutus across Rwanda, Burundi, and the Democratic Republic of Congo (Lemarchand, 2009; Prunier, 2008), that of Darfuris in Sudan and Chad (Behrends, 2007), and that of Ethiopians in Somalia, Eritrea, and Eastern Africa (see brief account by Calhoun, 1999) have all prompted greater theoretical sensitivity to how the ethnic cleansing of minority populations – and especially to their lives in resettlement or refugee camps – can carry conflicts across borders, and entwine them with those of other, equally vulnerable political contexts or disaffected populations. Indeed, the politicizing effects of displacement are particularly acute where displaced populations live in large refugee settlements that have a kind of semipermanent status, for example, the new identities and politics emerging in the camps of Somali refugees in Kenya or Darfuri refugees in Chad.

Ethnic Conflict, Geography of

Frederick W Boal, Queen's University Belfast, Belfast, Northern Ireland, UK

Abstract

Much ethnic conflict is territorially based. From a geographical perspective, ethnic conflict can be viewed at three scales – the interstate, the intrastate, and the predominantly micro-urban level. However, conflicts at these scales are intimately connected and interact with each other. The outcomes of conflict can produce secession, segregation, or at least some degree of separation of the groups concerned. Again, this can be viewed across a range of scale levels. A number of territorially based solutions or at least means of regulating ethnic conflict can be delineated – territoriality, dominance, and mutuality.

Ethnic conflict is a worldwide phenomenon. Much of it is territorially based, entailing disputes over the control of space. It occurs over a wide range of spatial scales, from the interstate level to the urban neighborhood. Violence takes place at the extreme, though a significant amount of ethnic conflict is characterized by nonviolent behavior. Causal factors can range from material welfare concerns to identity issues. A range of territorially based solutions or at least attempts at conflict regulation have been put forth.

Spatial Scales

It is possible, from a geographical perspective, to classify ethnic conflicts into three categories – the interstate, the intrastate, and the microscale or intra-urban. However, it must be stressed that there are powerful linkages between the various scales. Events at the interstate scale can reverberate down into individual states and may even have consequences at the level of urban neighborhoods. Likewise, conflicts at the urban microscale can impact at the larger spatial scales, even as far as triggering ill-feeling or worse, in the 'international' arena. No matter what the scale, spatial concentration appears to be very significant in providing a possible base for the generation of conflict. Monica Duffy Toft (2003) and others have suggested that there are two mechanisms at work here: motivation driven and opportunity driven. The first derives from the fact that groups with a high degree of spatial concentration are more likely to display a strong attachment to their territory and are, therefore, more likely to fight for it. Indeed, in some cases, the space may have almost become sacralized. The second mechanism requires a relationship between a group's concentration and its ability to develop and sustain collective organization for violence. Work by Nils Weidman (2009) indicates that the second – opportunity – mechanism is the stronger, though it can be argued that all this is a bit of a chicken-and-egg situation (chicken and egg both playing important roles), with loyalty/attachment to territory and the organizational benefits of spatial concentration forming part of an overriding, inseparable territorial nexus. In terms of cause and effect, it is also worth noting that while spatial concentration may be a possible generator of conflict, such concentration can actually be the product of conflict in the first instance.

Ethnic Conflict at the Interstate Scale

The geographical distributions of many ethnic groups do not conform neatly to existing state boundaries (the Basques and the Kurds provide clear examples of this). The misfit between state and ethnic group boundaries is stressed by Niall Ferguson (Ferguson, 2006: lv) when he notes that "in certain parts of the world there was [and is] an exceptional mismatch between ethnic identities and political structures." He points, in particular, to the ethnic map of eastern and central Europe between World Wars I and II. This mismatch between state and ethnic group boundaries may generate claims. As Donald Horowitz (1985: 281) has put it "if irredentism is conceived as a movement to retrieve ethnic kinsmen and their territory across borders, the common disjunction of group boundaries and territorial boundaries offers scope for irredentas aplenty." Horowitz further notes that a decision to attempt to forcibly retrieve ethnic group members across a border is, in the main, a government decision. This contrasts with secession, which is an ethnic group's decision to break away from the state that it currently finds itself penned into. Secession may involve an attempt to form a separate state, or it may mean breaking away from one state and joining another.

Stanley Lieberson (1972) has stressed that an ethnic group has the possibility of reducing or eliminating any disadvantage it may suffer, by opting for political separation. As he points out such a strategy is not available to other disadvantaged groups in a stratified society (for instance those disadvantaged on grounds of gender, age, or economic position). Thus, as Lieberson outlines it, the most fundamental difference between ethnic and other forms of stratification lies in the fact that the former is nearly always the basis for the internal disintegration of the existing boundaries of the state. Since the objective is most likely to be the formation of a new state, the best way to describe such secessionist groups is to refer to them as 'ethno-nationalists.' Such attempts at the disruption of existing states will not be greeted favorably by existing governments. Thus secession is likely to be pursued and to be resisted by the use of violence.

Interstate ethnic conflict also manifests itself through the roles of 'external national homelands' (Brubacker, 1996) and ethnic diasporas. With the former a state may feel an obligation toward its fellow ethnics in one or more other states. This obligation may translate into attempts to influence those other

states' policies toward the homeland state's co-ethnics, or to the offering of immigration and citizenship privileges for returning members of the ethnic diaspora. Involvement, however, may extend to irredentist claims. Ethnic diasporas, on the other hand, may express concerns about circumstances in their original (real or mythical) home countries. In this case elements in the diaspora communities will encourage their 'own' government to adopt policies that are perceived to be advantageous to fellow ethnics in the 'old country' or ethnic homeland. Irish Americans vis-à-vis Ireland, Jewish Americans vis-à-vis Israel, and Arab Americans vis-à-vis Palestine are clear instances of this. Indeed, some of these groups may well adopt stances that are more extreme than those taken by their fellow ethnics 'back home,' or as Samuel P. Huntington (1997) has put it, they may be 'more Catholic than the Pope.' Huntington also observes that diaspora communities become particularly active in the age of electronic communication: "the commitments of diasporas are reinvigorated and sometimes polarized by constant contact with their former homes." (1997: 274).

Ethnic conflict at the interstate level is also evident in what Samuel Huntington labels 'fault-line wars.' While these wars erupt at the interfaces between 'civilizations' (labeled by Huntington 'Western,' 'Islamic,' 'African,' and so on), they frequently involve localized ethnic groups, acting, as it were, as the standard bearers of their respective global-scale groupings. Of course, some of these fault-line wars occur at the intrastate level. In either case they are struggles for control of people and of territory.

Population transfers play a significant role in many interstate ethnic conflicts. If borders cannot be adjusted, people may be 'adjusted' instead. Sometimes the ethnic territories are 'purified' by agreement, as with the transfer of Greeks and Turks in the early 1920s. Frequently, however, transfers are achieved by expulsion or – the ultimate savagery – by genocide. Finally, it can be noted that some transfers are associated with what John McGarry (1998) calls 'demographic engineering' on the part of states. Here 'agents' may be moved in, being population allotted special roles on behalf of the state concerned; on the other hand some groups perceived as 'enemies' may be moved out, enemies being defined as groups whose present locations pose problems for the authorities and an obstacle to their goals (these goals generally being one of territorial control). As with all types of population transfer, these movements can occur both within and between states.

Ethnic Conflict at the Intrastate Scale

Gurr and Harff (1994), in their book on ethnic conflict in world politics, place ethnic groups in four categories – ethnonationalists, indigenous peoples, communal contenders, and ethnoclasses. Ethnonationalists are relatively large and regionally concentrated ethnic groups, which live within the boundaries of a single state or straddle several adjacent ones. They are likely to be seeking a greater degree of autonomy or even independent statehood. Indigenous people may also be seeking some degree of autonomy, but are particularly concerned about the discrimination and exploitation experienced at the hands of the more technologically advanced people who, by and large, control them. Communal contenders, unlike ethnonationalists, do not seek separation or secession; rather, they seek to share power in the governance of the state they reside in.

As with communal contenders, ethnoclasses seek equality. Unlike contenders, however, they are usually spatially dispersed, rarely having a well-defined territorial base (for example, where ethnic entrepreneurs operate in specialized, spatially dispersed economic niches). Consequently, in their case, strategies aimed at secession from the existing state or at seeking some degree of autonomy within it are not relevant.

Thus, while some ethnic group conflicts impinge at the interstate level, many are contained within one state and do not spill over 'international' boundaries. The roles played by dominant groups in these situations are crucial – they set the context for the other ethnic groups present. What Hennayake (1992) calls 'majority ethnonationalism' can generate a reaction in a situation he refers to as 'interactive ethnonationalism.' In a similar vein, Brubacker (1996) writes of 'nationalizing states' where dominant elites promote the language, culture, demographic position, economic flourishing or political hegemony of their own group, creating an environment disadvantageous to the cultural aspirations and material interests of the other ethnic groups present within the state. Indeed, here issues of inclusion and exclusion are encountered, seen at their most general in the distinction between 'civic' and 'ethnic' nationalism. With the former, the nation is ethnically inclusive of all those who subscribe to the nation's political creed. With the latter, the claim is made that an individual's deepest attachments are inherited, not chosen (Ignatieff, 1993). National identity is defined by ethnic identity – *ein Volk: ein Staat*. However, it must also be stated that the existence on the ground of a clear distinction between 'ethnic' and 'civic' has been questioned by the research of Hjerm (1998) and others.

The maintenance of political and social cohesion in multiethnic states will be possible under three contrasting circumstances: first, where we find civic nationalism to be dominant, second, where one ethnic group is dominant, and, third, where an external power exerts hegemony. This latter situation has been particularly prevalent where imperial powers have operated – from the British, French, German, Austro-Hungarian, and Russian empires of the nineteenth and early twentieth centuries to what Michael Ignatieff (1993) refers to as the Soviet and American joint *imperium* after World War II. However, with the collapse of all but one of these, the lid of the pressure cooker has been lifted and apparently solid states have fragmented (the Soviet Union and Yugoslavia being the most notable instances). This has led to the (re-)emergence of previously suppressed or slumbering ethnic groups. Such a reawakening has threatened the fabrics of many states, generating movements that call for varying degrees of separation (from secession to regional autonomy).

Ethnic struggles at the intrastate level, from time to time, have been characterized both by what may be called 'census wars' and by 'symbolic strife.' With reference to the former, Donald Horowitz (1985) has coined the phrase 'winning the census' – here there are concerns about existing (ethnic) demographic balances and future trends. As he puts it (p. 194) "numbers are an indicator of whose country it is." Census watching becomes an obsession; arguments occur regarding the accuracy of census enumerations, and in some cases ethnic

numeral balances are so sensitive that the census is abandoned (as happened, for instance, in Lebanon; see discussion below on demography).

Matters of symbolism also take on a huge importance in states with internal ethnic conflict. Raymond Breton (1984) argues that the symbolic order is a key component in constructing and maintaining a collective entity. A dominant ethnic group will attempt to impose its symbolic order on the state – flags, official language, anthems, and so on. Other ethnic groups may resist this process, with the consequence that many symbols become contested and contribute to disunity. Ethnonationally contested spaces, in particular, are notable for their symbolic dissensus. Of course, symbols may well help create unity within a particular ethnic group, but in terms of inter-ethnic relations they divide.

Within-state ethnic conflict may arise between indigenous or well-rooted populations, on the one hand, and recent, less well-rooted immigrants on the other. If the immigrant flow is overwhelming (numerically or technologically) the indigenous ethnic group(s) will find themselves marginalized (as was the case in North America). However many immigrant flows have to accommodate themselves to the preexisting social and political environments. In this case, conflict will be over equality of treatment – the immigrant will not expect (or presumably wish) to take over the state that receives them.

Ethnic Conflict at the Microscale

Ethnic conflict gains its greatest intensity at the small scale – here individuals and small groups interface with each other as part of the daily round. Rural, relatively low population density environments can experience intense conflict (as well as day-to-day coexistence), but it is usually in the urban, big city environments that ethnic antagonisms can achieve a peculiarly focused, 'molecular' nastiness.

In the urban context, foreign origin migrants attempt to establish themselves as do those from within the state, some of which may also have their origins in ethnically differentiated regions. While conflict is not necessarily an inevitable outcome, it is of frequent occurrence, as the migrants compete with each other and with the receiving society for scarce resources of housing, employment, educational opportunities, and so on. In these circumstances many ethnic newcomers experience a degree of residential segregation, part based on the wishes of the immigrant and migrant ethnics themselves, part based on the somewhat hostile response of those who see themselves as the 'hosts.'

From a bottom-up perspective, ethnic groups may be seen to cluster together residentially for reasons of physical defense, from a wish to distance themselves from the embarrassment of contact with ethnocentric others, and, indeed from a wish to have a base for organizing politically and, thereby, gaining a say in the decision making in the wider society through judicious use of the electoral system. In the more extreme conflict environments, the segregated residential cluster can provide a base for organizing physical attack against a wider society that is seen to be oppressive. This is where the urban guerrilla is most likely to thrive. Finally segregation can provide a context for cultural preservation, one where the ethnic culture can be tended and, indeed, transmitted to future generations. Some of this clustering is for very positive reasons, but conflict can also be a key generating factor (Boal, 1987).

From the viewpoint of the encompassing society, segregation also has its merits – it provides a means of containing 'alien' populations, it insulates host culture from what may be perceived as undesirable influences, it provides a means of manipulating and minimizing the electoral impact of the immigrant ethnics and, at the extreme, it sets up the ethnic clusters as readily definable targets for attack. Beyond the urban scale, Nurit Kliot (1986) refers to intermingled ethnic clusters in Lebanon as 'hostage situations.' The same situation can apply at the urban scale.

Much ethnic conflict at the urban scale is relatively low key, entailing competition for access to the resources of everyday life and frictions over cultural matters. However, some cities become cockpits of ethnonational strife. In this situation, local conflicts and competition become embroiled in issues of sovereignty, and are thereby greatly intensified. Meron Benvenisti (see Bollens, 2000) has labeled such cities 'polarized,' while Joël Kotek (1999) has applied the term 'frontier.' According to him, frontier cities are above all disputed places because they are subject to contradictory and opposing sovereignty claims. For Kotek, a frontier city is "a territory for two dreams."

The urban encapsulation of ethnonational conflict may be seen as the city merely mirroring wider conflicts over sovereignty, secession, irredentist claims, and desires for regional autonomy. More accurately, cities displaying ethnonational encapsulation are, in reality, key players in the conflicts in their own right. Examples such as Jerusalem, Belfast, Brussels, Montreal, Nicosia, and Sarajevo make the point. Indeed some of these cities are the epicenters of the wider conflict and are the focus of particularly intense ethnonational disputation. Jerusalem stands out in this regard.

Demographic Balance

A factor with the potential to trigger ethnic conflict, operating at all geographic scales, is the influence of demographic balance. At the state level, demographic balance between competing ethnic groups can be very significant in terms of power within the political system. Shifts in demographic balance can be seen as zero-sum situations – one group's gain is the other group's loss. Such shifts in demographic balance are generated by differential birth rates (the ethnic conflict is won or lost in bed; at one time in Québec this was referred to as *la ravanche des berceaux*), differential death rates, or by differential migration flows (voluntary or forced), or by the combined operation of two or more of these processes.

At the regional and urban scale levels, demographic balance can also be very significant, where one group may use its majority position to impose its cultural norms and to shift resource distribution to its advantage (housing, employment, educational resourcing, and municipal services) Slack and Doyon (2001: 158) encapsulate all this in their discussion of Bosnia, claiming that "when ethnonationalism becomes a political force, demography matters." They go on to note that "the threat of decline of one group at the expense of

another further aggravates the pressure for interethnic conflict."

To repeat: the significance of demography needs always to be judged within a series of spatial frameworks – state, region, city, or neighborhood.

Conflict Regulation and Resolution

Solutions to ethnic conflicts can take a number of forms – territorial approaches, dominance approaches, and mutuality approaches. Territorial solutions entail actions that increase the ethnic homogeneity of specified territorial spaces. The most extreme approaches involve the removal – by genocide or by forced population transfer – of one or more ethnic groups, producing what might be called 'purified' spaces. More acceptably, territorial approaches can involve the creation of separate states for each ethnonational group (partition or secession), or for cantonal or federal arrangements within the one state. Of course processes of integration/assimilation can also remove differences within a given state. If these occur by consent, then interethnic relations are likely to be positive; if they occur in a coercive manner the consequences will be alienation and the consequent storing up of future conflict.

Dominance is where hegemonic control is exerted by the most powerful group present in a multiethnic environment. It is unlikely to provide a long-term solution to interethnic conflict – rather it suppresses it, leading to a situation where one is likely to find reluctantly acquiescent ethnic minorities at best and considerable alienation at worst.

Mutuality is where ethnic groups in conflict reach a point where they are prepared to enter into a process of mutual recognition and acceptance. Consociational/power sharing arrangements within the state will be the outcome. In this situation we would find what has earlier been referred to as civic nationalism. Space is shared in a process of mutual accommodation (see discussions in O'Leary and McGarry, 1995; in Boal, 1999). Indeed, as suggested by Staub (2013), even in severe situations such as genocide, measures can be undertaken to achieve reconciliation.

This article is a revision of the previous edition article by R.M. Williams, volume 7, pp. 4806–4810, © 2001, Elsevier Ltd.

Abstract

The literature on ethnic conflict has mushroomed in the past three decades, but, despite a large volume of analytical output, important questions remain unanswered. There is no consensus on how this term is to be defined, nor is there full agreement on the identification and classification of cases. Nevertheless, there is substantial overlap between major cross-national data collections, and these have facilitated research into the causes and consequences of ethnic conflict. The associated qualitative literature has helped to advance both academic research in the area and policy relevant exploration of paths toward ethnic conflict resolution.

The study of conflicts labeled 'ethnic' has emerged only relatively recently as a major focus of research, though the phenomenon to which it now refers may well have been analyzed earlier using different terminology. During the two decades 1970–89, which were marked by many instances of domestic strife that would today be described precisely as 'ethnic conflict', only nine academic articles bearing this expression in their title are recorded in the Scopus bibliographical database, out of more than 600 000 English-language articles in the area of the humanities and social sciences. During the 1990s, however, this exploded to 94 articles, and in the first decade of the twenty-first century it expanded further to 164 articles (out of a total of 1.8 million English-language articles in the humanities and social sciences). More broadly based bibliographical tools, such as Google Scholar and library catalogs, report a rather greater number of items, but here, too, the proportionate upsurge in interest in the 1990s is obvious.

Any effort to generalize about this burgeoning literature needs to start by noting that the expression 'ethnic conflict' itself gives rise to a range of potential challenges. These include problems of definition (in that each of the two words in the expression lacks an unambiguous meaning), difficulties of description (since even listing and outlining the parameters of cases of ethnic conflict take us into disputed terrain), issues of explanation (because differing theoretical perspectives lead to varying conclusions as to how ethnic conflict is to be accounted for), and disagreements over outcomes (as conflicting empirical data and theoretical expectations lead to incompatible conclusions about the manner in which ethnic conflict is managed). This article considers these matters in turn.

Definition

Efforts to define 'ethnic group', and related terms such as 'nation', have had a long and unhappy history. Walker Connor (1978) summarized the dilemma in the title of a much-cited article, 'a nation is a nation, is a state, is an ethnic group, is a …', and the definitional problem has been addressed over the years in the social science literature (for example, McKay and Lewins, 1978; Brown, 1993: 4–5; Chandra, 2006). Authoritative international bodies have tried to bring intellectual order to bear, as in the case of UNESCO's glossary in the area of 'ethnic questions' (UNESCO, 1977) and a parallel initiative by the Research Committee on Conceptual and Terminological Analysis of the International Social Science Council (Riggs, 1985). Individual scholars have also sought to tackle the question by compiling comprehensive lists (for example, Spira, 1999).

The need for an agreed terminology is acute not just in scholarly analysis but also in public policy making. The legacy of efforts to clarify language in this area in the former Soviet Union, with its complex ethnically mixed population, is still to be seen in certain communist-run states such as China. Soviet nationalities policy, developed in the early twentieth century and adopted in much of the communist world, required the formal identification of ethnic groups, since they were seen as entitled to institutional recognition. Soviet terminology thus came to reflect a hierarchy of organizational forms, ranging from the most developed collectivity, the 'nation', through 'nationality', 'ethnic group', and 'ethnographic group' (Connor, 1984: 217–239; Fedoseyev et al., 1977: 17–50).

Eventually the challenge of identifying ethnic groups struck western policy makers too – they needed data on ethnic divisions with a view to designing specific policy initiatives (for example, in promoting measures to reduce inequality). By the early twenty-first century many states that had apparently been blind to ethnic difference in the past now began to invite residents to respond in the population census to questions about their ethnic (and sometimes 'racial') background. For example, the US census of 2010 asked two such questions: 'Is person X of Hispanic, Latino, or Spanish origin?' and 'What is person X's race?' (Humes et al., 2011: 1). The English and Welsh census of 2011 asked two similar questions: 'What is your ethnic group?' and 'How would you describe your national identity?' (ONS, 2012: 12–13). In Canada, the corresponding question in 2011 was 'What were the ethnic or cultural origins of this person's ancestors?' (Statistics Canada, 2013: 5). These questions may have been confusing, but in each case the range of precoded response categories made the task of respondents easier, even if it meant forcing them into boxes defined by census takers. Survey research analysis has engaged in a similar struggle to measure ethnic identity, but without reaching a consensus on a single, preferred method to

tackle this extremely challenging question (Coakley, 2007: 581–583).

Efforts to resolve the terminological problem by inventing entirely new words have been less than successful. For example, Anthony Smith (1971: 187–191) adopted the French term 'ethnie' as an alternative, and Pierre van den Berghe (1981: 22) used a similar noun, 'ethny'. But these terms failed to be widely adopted. Arguably the only case where new terminology made an impression on the lexicon of ethnic studies was Walker Connor's (1994) popularization of the terms 'ethnonational' and 'ethnonationalism'; but these have rather more specific meanings than 'ethnic'. To facilitate further discussion here, it may be appropriate simply to adopt a stipulative approach, and to define an ethnic group as 'a large collectivity whose members are linked by certain cultural characteristics – including sense of sharing a common past – which they and others see as defining a social boundary between members and nonmembers of the group' (Coakley, 2012: 11). This of course leaves certain loose ends (it is not clear what 'large' means, or how 'cultural' characteristics may be measured); but it helps to narrow the parameters of what is at stake.

Because of these difficulties of terminology, determining when a conflict is 'ethnic' is far from straightforward. Of course, ethnic identity and conflict are symbiotically related; it has for long been acknowledged that social conflict feeds on differentiation, but also shapes it (see Coser, 1956). When, though, is a confrontation between two or more ethnic groups actually a 'conflict'? Does a purely latent 'conflict' merit that description? For example, outside observers and some insiders may perceive an apparently objective, fundamental conflict of interest between two ethnic groups, as when two such groups coexist in circumstances of deep social stratification. But conflict of interest would not necessarily be widely interpreted as real 'conflict', and a particular point along a scale must be used to define the moment where tension and disagreement spill over into conflict (for an overview of approaches toward explaining this transition, see Opp, 2009). Sidestepping the issue of intensity, one useful definition sees ethnic conflict as referring to 'situations in which combatants take recourse to the systematic use of violence for strategic purposes and in which at least one combatant defines itself primarily in relation to a distinctive ethnic identity' (Cordell and Wolff, 2011: 4). This, of course, still leaves the cutoff point undefined, and researchers are by no means unanimous in responding to this, as will be seen in the next section.

Description and Classification

One of the clearest illustrations of the debilitating consequences of the terminological confusion discussed in the last section is the set of difficulties that encounter the researcher who seeks to identify and classify cases of ethnic conflict. Ethnic conflicts are of course a subset of political conflicts more generally, so it is appropriate as our starting point to look at the major cross-national data collections that exist in this area, and then to assess their value as instruments for the compilation of exhaustive lists of cases of ethnic conflict.

One of the earliest attempts to offer a systematic, quantitative approach to intrastate (and, indeed, interstate) conflicts was the path-breaking study by David Singer and Melvin Small (1972) of the 'correlates of war' (COW). This evolved subsequently into a major database of intrastate wars and of participants in these, spanning the period 1816–2007 (Sarkees and Wayman, 2010). Two other early American projects with an overlapping agenda supplemented and in certain respects competed with this. One, the 'Polity' project, focused on political system characteristics and variables accounting for stability and change (Eckstein and Gurr, 1975). Its current version (Polity IV) extends over the period 1800–2012 (Marshall et al., 2013). The second had a more specific concern with minorities: the 'Minorities at Risk' project, which concentrates on minorities that have achieved a minimum degree of political mobilization (see Gurr et al., 1993; MAR, 2014). While of themselves these two data sets do not code conflict, they have been used as a basis for other collections which do – for example, in the case of the work of Fearon and Laitin (2003), or the 'major episodes of political violence' (MEPV) data set developed by Monty Marshall (2013).

This body of data has been reinforced by parallel programs in Europe. Two examples may be cited. First, as part of a strong Scandinavian tradition of peace research, the Uppsala Conflict Data Program (UCDP) and the International Peace Research Institute, Oslo (PRIO) have produced – among other related data sets – successive editions of an 'armed conflict' data set spanning the years since 1945 (Gleditsch et al., 2002; Themnér and Wallensteen, 2013). A second widely used data set has emerged from the Heidelberg Institute for International Conflict Research (HIIK), which produced a regularly updated 'Kosimo' ('conflict simulation model') data set (Pfetsch and Rohloff, 2000), though in its reconfigured version it is not currently publicly available. These by no means exhaust the range of such data sets, but are sufficiently diverse to illustrate the issues of measurement that arise.

Of course, many data collections sidestep difficulties of measurement by relying mainly on qualitative reporting: the *Encyclopedia of Modern Ethnic Conflicts* (Rudolph, 2003), for instance, the *Encyclopedia of Ethnic Relations* (Levinson, 1994), and the various editions of *Mondes rebelles* (Balencie and de La Grange, 2005). But most of the programs already mentioned typically present a large volume of qualitative descriptive material alongside the quantitative indicators. Some are associated with the COW data set (for example, Sarkees and Wayman, 2010). MAR (2014) maintains a set of valuable online reports on the minorities included in its quantitative data set. The Polity IV Project (2014) produces a set of regularly updated country reports. Qualitative reports on armed conflicts have appeared annually since 1993 in PRIO's *Journal of Peace Research* (normally in the penultimate issue), parallel to an online *Conflict Encyclopedia* maintained by UCDP (2014); and HIIK (2014) has published a detailed annual *Conflict Barometer* since 1992 (in German in the early years, but in English from 2002 onwards).

These collections, however, immediately highlight significant problems of definition and classification: as well as varying interpretations of conflict and of cutoff points for inclusion, different data sets classify conflicts in different ways as regards their substantive basis (such as the extent to which they are 'ethnic') and their levels of intensity. If we select four of

the data sets discussed above, a brief description of their approach to definition and classification will highlight this point. They define their primary elements of analysis as follows:

Correlates of War (COW): Intrastate wars are wars that are fought within state borders between a government and non-government forces (civil war), or at least two non-government forces (intercommunal war) … in order to be classified as a civil war, the central government should be actively involved in military action with effective resistance for both sides, and there should be at least 1000 battle related deaths during the civil war.
(see Sarkees and Wayman, 2010)

Major Episodes of Political Violence (MEPV): Major episodes of political violence involve at least 500 directly-related fatalities and reach a level of intensity in which political violence is both systematic and sustained (a base rate of 100 directly-related deaths per annum).
(Marshall, 2013: 7)

Political conflicts (HIIK – Kosimo): Conflict is defined as the clashing of opposing interests or positional differences around national values and issues (independence, self-determination, borders and territory, access to or distribution of domestic or international power). A conflict has to be of some duration and is carried out between at least two parties (states, groups of states, organizations or organized groups) that are determined to pursue their interests and win their case. At least one party is the organized state.
(Pfetsch and Rohloff, 2000: 386)

Armed conflicts (UCDP–PRIO): An armed conflict is defined … as a contested incompatibility that concerns government or territory or both where the use of armed force between two parties results in at least 25 battle-related deaths. Of these two parties, at least one is the government of a state.
(Gleditsch et al., 2002: 618–619)

The associated data sets, and their classification systems, are summarized in **Table 1**. It will be seen that the four data sets have different criteria for classifying conflict types. Two (MEPV and Kosimo) recognize a specifically 'ethnic' category, and the Kosimo data set handles the problem of complex cases by using a multiple coding system that allows conflicts to be simultaneously classed as falling into more than one category. In the case of COW, the 'intercommunal war' category overlaps very substantially with that of ethnic conflict, but the addition of a second category ('civil war over local issues') captures other ethnic-type cases without being excessively inclusive. In the case of the UCDP–PRIO data set, the two-dimensional classification system (incompatibility type and conflict type) seems promising at first, in that restricting cases to internal conflicts directed at territory seems plausible; but the 'incompatibility' dimension is of limited value in identifying an ethnic category, since most of the internal conflicts which were classified as being directed at 'government' rather than 'territory' clearly had an ethnic component.

The data sets vary also in their approach to measuring conflict intensity – a recurring problem in the analysis of civil wars (Sambanis, 2004: 815). The Kosimo data set is the most sensitive to conflicts of all kinds: it equates these with clashing interests, even if no deaths result. For example, the smouldering but latent Flemish-Walloon conflict in Belgium (whose high point as regards violence was reached in early 1968, when Flemish students rioted and threw 'Molotov cocktails' in Louvain) is included only in this data set; indeed, its sponsoring body, HIIK, monitored no fewer than 58 conflicts in Europe alone in 2012, though most were at a low level of intensity (HIIK, 2013: 4). For the UCDP–PRIO data set, a threshold of 25 battle deaths is stipulated; this rises to 500 in the MEPV data set, and to 1000 in COW.

Table 2 presents a comparison of the four data sets in respect of their reporting of what might be defined as ethnic conflicts, broken down by continent. To enhance comparability, a standard start date (1945) is taken, thus eliminating most of the cases in the COW project, which begins in 1815. The closing date ranges from 1999 to 2012. It is possible to identify categories in these data sets that approximate ethnic conflicts (though not necessarily using this label in all cases). The much lower numbers recorded by COW and MEPV derive from another inconsistency in approach across the data sets. The 'episodes' that they identify are inclusively defined: a long-running conflict with shifting participation by actors still counts as just one conflict. In the case of UCDP–PRIO, by contrast, coding is highly sensitive to any change in participants, and as coded here such a change results in the identification of a new conflict; but, in addition, it is likely that some cases have been included here which are not ethnic conflicts at all.

These data sets, then, have some value in generating a checklist of potential cases of ethnic conflict, and it is relatively easy to whittle that down to plausible cases. It is true, as Eck (2008: 39) argues, that these different but overlapping definitions result in potentially incompatible and confusing lists of cases, since this diversity 'illuminates not only the theoretical disagreements regarding what conflict is, but has produced confusion in interpreting the statistical COW'. But she regards this position as preferable to the homogeneity that would emerge from use of a single definition in circumstances where there is no consensus about what conflict is – a healthy warning against naïve attempts to believe that a list of such conflicts on which all would agree might ever be drawn up.

Explanation

Why do ethnic conflicts break out? This straightforward but virtually unanswerable question breaks itself down into at least three subordinate questions. First, how do population groups come to see themselves as ethnically related – in other words, what explains the transition from a social category sharing certain linguistic, religious, cultural, or phenotypical features to a self-conscious ethnic group? Second, in what circumstances does an ethnic group become politically mobilized, making demands on the state that set it in conflict with other groups? Third, what causes a politically mobilized ethnic group to abandon conventional political processes and move to the use of physical force in advancing its objectives?

There is substantial agreement on the broad parameters of an answer to the first question, about the manner in which self-conscious ethnic groups come into existence. The appearance of such groups may be explained in part by the impact of differential social and economic dislocation on

Table 1 Overview of four conflict data sets

Substantive types	*Levels of intensity*	*Cases included*
Correlates of War, version 4.1, 2011		
(1) civil war for central control; (2) civil war over local issues; (3) regional internal war; (4) intercommunal war	Duration in days, and number of battle deaths	Intrastate wars, 1816–2007; N = 442
Major Episodes of Political Violence (MEPV), 2012 ed.		
(1) International; (2) international independence; (3) civil; (4) ethnic; each except the second is divided into two subcategories, 'violence' and 'war'	Intensity of either violence or war along a 10-point scale from low to high	Country – years, 1946–2012; 329 episodes; N = 9057
Political conflicts (HIIK–Kosimo), 1999 ed.		
Conflict over (1) territory, borders, sea borders; (2) decolonization, national independence; (3) ethnic, religious or regional autonomy; (4) ideology, system; (5) internal power; (6) international power; (7) resources; (8) other; multiple categorization possible	Four levels: (1) latent conflict – completely nonviolent, open verbal claims; (2) crisis – nonviolent, more intensive claims; (3) severe crisis – sporadic irregular use of force, blockade, threat; (4) war – organized continuing use of force	Political conflicts, 1945–99; N = 641
Armed conflicts (UCDP–PRIO), version 4-2013		
Two incompatibility types: (1) directed at the government or political system; (2) directed at the territory, as in demands for autonomy or secession; further distinction between four conflict types: (1) interstate; (2) extrastate (including colonial and imperial wars); (3) internationalized internal armed conflict; (4) internal armed conflict	(1) Minor (at least 25 battle deaths per year, but fewer than 1000 overall); (2) intermediate (25–999 per year, but more than 1000 overall); (3) major (at least 1000 per year)	Conflict – years, 1946–2012; 253 conflicts; N = 2098

groups defined by distinctive cultural or other features, and by population movement processes or geopolitical changes (such as military conquest) that bring culturally differentiated groups into close contact with each other. Sudden, substantial movement from the countryside into culturally alien towns, or migration across countries, may in certain circumstances promote the emergence of a collective identity that distinguishes the 'new' group from the earlier settled population – a population which, in turn, may itself find a new sense of collective identity in the face of 'alien' newcomers. Imperial expansion and territorial boundary change may bring similar consequences. While scholars are divided as to the process by which this identity transformation takes place, and the factors that govern it, few, if any, now subscribe to the view that this is a 'primordial' process, driven by innate characteristics within the coexisting groups (Coakley, 2013).

The second question attracts less consensus: how does a previously dormant ethnic group become politically mobilized, making specific and determined policy demands on the state? Structural features (such as growing socioeconomic inequalities) may play a role, but perception of such features is critical. It is normally social, cultural, or political leaders who highlight issues of these kinds; indeed, elites play a central role in this stage of the mobilization process, whether by highlighting the 'injustices' under which subordinate groups labor, or by pointing to the 'threat' to the position of dominant groups that other ethnic groups represent. For new immigrant minorities, marked by varying levels of integration in the host society from generation to generation, from country to country, and from city to city, immediate barriers to social advancement may color attitudes toward the state, and in certain configurations lead to forceful dissent, whether in the form of rioting or by more structured means. Ethnic mobilization may take the form of a new, urban middle class moving into a leadership role, but in other

circumstances religious elites are decisive actors, and dominant groups can rely on the military, the bureaucracy and the aristocracy (groups unevenly represented from case to case) as important resources.

Finally, in what circumstances does a transition take place from electoral dissent or peaceful protest to violent rebellion or intergroup warfare? To start with, there may be circumstances where peaceful or 'constitutional' routes simply do not exist: subordinate groups have no access to legal channels for advancing their demands, either because the state is an authoritarian one, or because these rights are withheld from them, either explicitly or through the use of surrogate exclusionary criteria. Alternatively, even if the conventional electoral or conflict-resolving devices of a liberal democracy are available, one group may feel that it is consigned to permanent minority status, so that armed rebellion is the only alternative to being permanently outvoted in a state whose legitimacy is leaders question. Conversely, the leaders of dominant groups may see violent repression of dissident minorities as the only appropriate response in defending their interests (which they typically represent as the interests of the state). Alongside rational choice-type explanations for the outbreak of ethnic conflict, social psychological theories (focusing on matters of collective identity and security) have much to contribute; and the role of external intervention also needs to be borne in mind (Cordell and Wolff, 2010: 25–43).

Outcomes

How do ethnic conflicts evolve? In what circumstances do they simply bubble on, whether marked by low- or high-intensity violence? How are they sometimes brought to an effective end? Often, the outcome is a consequence of the uneven nature of the conflict between the two sides: the conflict in its overtly violent form is brought to a conclusion by the military victory of one side rather than through a negotiated deal (Licklider, 1995: 684). The defeat of the Tamil Tigers in Sri Lanka in early 2009, signaling the decisive victory of the other side, is an instance. Yet there are more positive examples, where contending parties have managed to hammer out a deal that persists at least in the short and medium term, as in South Africa and Lebanon.

In the case of such negotiated settlements, the central dilemma has been expressed pithily by Roy Licklider (1995: 681): 'how do groups of people who have been killing one another with considerable enthusiasm and success come together to form a common government?'. The issue is not just agreement but also durability: peace settlements after prolonged ethnic conflicts may be particularly fragile. There is a strong tendency for civil wars to reignite even after a settlement, with half of all negotiated agreements breaking down within 5 years (Licklider, 1995: 685). Comparative research points to the general factors that matter: the intensity and character of violence, the capacity of domestic political actors to manage this, and the effectiveness of external forces in intervening (Doyle and Sambanis, 2000). One comprehensive overview of the literature identified a set of background circumstances that are likely to have an impact, in one direction or another, on the survival prospects of a peace settlement (Hartzell et al., 2001: 188–190):

- *Historical period* (agreements reached after the end of the Cold War are more likely to persist, since the actors are less likely to be proxies for rival great powers)
- *State tradition* (agreements within states with a democratic tradition are more likely to last, since elites have more extended experience of political accommodation)
- *Character of underlying cleavage* (agreements between groups divided by ideological considerations are more likely to survive than those between contending ethnic groups, since it is easier to establish a middle ground)
- *Intensity of conflict* (agreements at the end of a low-intensity conflict are more likely to survive, since if conflict intensity has been high the level of continuing mutual suspicion is likely to be greater)
- *Duration of conflict* (agreements that conclude a long conflict are more likely to endure than those which conclude a short conflict, since protracted war is more likely to highlight the attractions of the political path).

The same authors add that the content of the agreement itself also matters. First, agreements that provide for territorial autonomy are more likely to succeed, since the most politically sensitive issues can be defused by allowing each group to adopt its favored formula in its own area, a stable balance between the groups can be established, and additional resources can be made available at substate level. Second, agreements that allow for third-party enforcement are more likely to endure, since they serve to reduce the security concerns of the parties to the conflict and provide a mechanism for intervention at critical moments (Hartzell et al., 2001: 191–193).

These points take us close to the ultimate political design of a society in which ethnic conflict has been substantially resolved, regardless of the means by which this has been brought about. To what extent may we see predictable patterns here? Some analysts cast the net very wide, identifying a range of endpoints for ethnic conflict, from elimination through genocide to accommodation through formal institutional recognition of difference (for example, Horowitz, 1990; Coakley, 1992; McGarry and O'Leary, 1993; Schneckener and Senghaas, 2003: 166–167). For others, the only 'solutions' that merit the description are those where a formula for stable government has been reached and generally accepted (for example, Zartman, 1990; Smooha and Hanf, 1992; Cohen, 1997; Peleg, 2007: 78–83).

These authors collectively produce a long list of approaches, but two dimensions seem to underlie these: the degree to which they rest on a generous regime of individual rights, and the extent to which they acknowledge groups as important components in society. The broad outcomes may be summarized by considering four combinations of positions in respect of these dimensions (Coakley, 2012: 219–239).

- Elimination: Neither individual rights nor collective existence are acknowledged; subordinate ethnic groups are physically removed in a process of 'ethnic cleansing', as in the genocide of most of Europe's Jewish population during the Second World War, or the expulsion of the German populations of Poland and Czechoslovakia after the war.

- Exclusion: Individual rights are not acknowledged, but there is some recognition of group identity. Minorities are, however, excluded from mainstream political life and may be given restricted forms of autonomy, as in the 'homeland' policy of South Africa under apartheid.
- Integration: Full individual rights are recognized, but the existence of subordinate ethnic groups is denied. All of the population may share fully in the government of the state, but must do so by accepting the norms and values of the dominant culture. This may mean the assimilation of minorities, as in the traditional model of the Jacobin state in France, or the 'melting pot' metaphor in the USA.
- Accommodation: Full individual rights are conceded, but group rights are also recognized. This may result in such strategies as power sharing government (or consociation), territorial autonomy, or nonterritorial autonomy (contemporary Belgium illustrates all three approaches).

Conclusion

The difficulties of definition that have impeded the analysis of ethnic conflict are reflected in the discussion above, and in the nature of the quantitative data sets that have been described. Valuable though such data sets are, it is almost impossible to avoid also introducing qualitative considerations, and the rich supplementary descriptive text material presented as additional documentation for these data sets is of central importance. In the first place, it allows us to whittle down the number of cases by excluding those which clearly do not have a significant ethnic dimension (though there remain some marginal cases). Second, it draws attention to cases that have been excluded from the quantitative data sets. The very extensive associated analytical literature that has developed in the past three decades provides the materials for substantial progress in exploring the causes and consequences of ethnic conflict, and in identifying possibly pathways toward settlement. While theoretical disagreements will continue, there is at least scope for limited progress within particular theoretical frameworks in arriving at a balanced understanding of a phenomenon whose implications for societal harmony are so potentially devastating.

Ethnic Identity and Ethnicity in Archaeology

Margarita Díaz-Andreu, ICREA-Universitat de Barcelona, Barcelona, Spain

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In this article, ethnicity is defined as that aspect of a person's self-conceptualization and his or her conceptualization by other individuals that results from identification with one or more broader groups, on the basis of perceived cultural differentiation and belief in a common descent. This definition understands ethnicity as multidimensional, situational, and fluid and makes its link with material culture much more complex than traditionally perceived. Within the last decade, the term 'community' has been introduced into archaeology to refer to a social collective that shares a geographical space and many have agreed that it is a useful concept. For archaeologists, talking about communities instead of ethnic groups circumvents the problem of assigning an ethnic identity to groups for which only material culture remains.

Many may think that the study of ethnicity is a recent topic in archaeology, but this is only partially true. Archaeologists have always been involved in the identification of ethnic groups in the past, but have defined these groups using different terms. In the early years, archaeologists called ethnic groups 'peoples' and 'nations,' terms that were replaced with 'archaeological cultures' from the start of the twentieth century (Díaz-Andreu, 1996). It is only since the 1980s that the growing influence of anthropology (*see* Ethnicity: Anthropological Aspects) on archaeology has persuaded the latter to begin to talk about ethnicity and ethnic groups.

Ethnicity will be defined here as that aspect of a person's self-conceptualization and his or her conceptualization by other individuals that results from identification with one or more broader groups, on the basis of perceived cultural differentiation and belief in a common descent (Díaz-Andreu, 1998: p. 199, see also Jones, 1997: p. 1). However, not all scholars would agree with this definition. It does not focus on the ethnic group in itself as something objective and describable, as many archaeologists would like. Far from it, the definition provided here stresses perception and, although it does not intend to deny commonalities among the members of the same group, including race (*see* Race: Ethnicity, and Health), it does not consider them a fixed set of cultural rules agreed by all members of the ethnic group.

The above definition considers ethnic identity (*see* Identity and Identification) as multidimensional, because it argues that people can identify with one or more broader groups. It proposes, therefore, that multiple ethnic affiliations usually coexist and overlap in the same person. Each individual is (or is potentially) associated with various groups that could be classed within the definition of ethnicity. An example from Europe would be a Mancunian, who may feel themselves to be a Mancunian, English, British, European, or a world citizen. They can even be of Pakistani descent. However, because of our political education, if asked for their ethnic identity, this person would provide a single answer, selecting only one ethnic identity. This reaction has been expected from each citizen since the end of the eighteenth century. However, this might not necessarily be what people feel and what people felt in the past or in non-Western societies (Metcalf, 2010).

Two more aspects may be added to the proposed definition of ethnicity. The first is that ethnic identity can be described as situational. Each of these complementary and enriching ethnic identities can come into play individually in various situations, depending on where the people are, what the situation is and what political ideology they hold. Each individual is active regarding his or her ethnic identities and the daily negotiations will entail that one or several of them are made manifest. Second, ethnic affiliations are fluid. They are and have been in a continuous process of flux, as is reflected by the appearance and disappearance of group names throughout the several centuries referred to in written sources.

Within the last decade, the term 'community' has been introduced into archaeology to refer to a social collective that shares a geographical space (Canuto and Yaeger, 2012; Mac Sweeney, 2011). Communities are seen as groups of individuals held together by living together in a settlement, and also by practices of affiliation: shared ways of acting and behaving, a common understanding of the social meaning of objects, agreement on routines of consumption, exchange, and the curation of material culture and the physical setting in which practices should take place. Some authors have greeted the arrival of this concept as an acknowledgment that not all group identity is necessarily bound by ethnic ties. However, one could also see the use of this concept as a way of circumventing the problem of assigning an ethnic identity to groups for which only material culture remains. It would be possible to argue that community identity may or may not have an ethnic component. Faced with a lack of written information that can inform about the feelings and identity belief of the individuals in a group, archaeologists are on safer ground talking about community rather than ethnic identity.

Of the two theoretical approaches currently predominant in the study of ethnicity, the primordialist and the instrumentalist (Jones, 1997), the conceptualization of ethnicity provided above fits in with the latter. The primordialist perspective considers ethnicity as something inherent, acquired by birth. Thus, the instinctive attachment of the individual to his or her territory and culture is emphasized and the ethnic group is regarded as the natural universal unit of human organization. The instrumentalist perspective, however, views ethnicity as a fluid and situational group identity. It is through practice that individuals perceive and negotiate their ethnic allegiances. This perspective stresses the social aspect

 http://dx.doi.org/10.1016/B978-0-08-097086-8.13032-6

of ethnicity as a regulatory device for social behavior and social organization within each ethnic group and between different ethnic groups. Archaeology has traditionally perceived ethnic identity from a primordialist stance and it is only in the last two decades that the instrumentalist viewpoint has made its appearance.

Archaeological discussion of ethnicity has a long record. Throughout much of archaeology's history, material culture has been understood in a very straightforward manner as a basis for inferring ethnicity. The presence of specific types of material culture and the absence of others have been considered as diagnostics to define groups. For example, the characteristic prehistoric incised beaker pot was seen to indicate the presence of the Beaker culture in an area and, similarly, Samian pottery attested the presence of Romans. This way of looking at ethnicity has been dominant from the early days of archaeology, although it was only clarified theoretically at the turn of the nineteenth century and in the early twentieth century by approaching it from the cultural historical point of view. Culture history first appeared in Austro-German anthropology (Zwernemann, 1983). It was adopted in archaeology a decade later, mainly through the work of the German archaeologist Gustaf Kossinna (Trigger, 1980: p. 44). The preeminence of German archaeology at this time favored the spread of the theory elsewhere. However, anthropology has long worked with a concept of 'culture' (Jenkins, 1997), whereas archaeology has only very recently been rethinking its use of 'culture' and beginning to explicitly discuss, problematize, and theorize ethnicity.

Within the cultural historical perspective, ethnic groups were called cultures (or civilizations in the case of non-primitive societies). The first definition of culture was proposed by Childe. As he put it, "we find certain types of remains—pots, implements, ornaments, burial rites, house forms—constantly recurring together. Such a complex of regularly associated traits we shall term a 'cultural group' or just a 'culture'" (Childe, 1929: pp. v–vi). In Childe and other culture historians' views of culture/ethnicity, there was no place for fluidity and negotiation, nor for perception. One could say that, in practice, archaeologists considered peoples almost as a by-product of objects. For example, changes in material culture were often interpreted as a result of invasions, i.e., as the substitution of one ethnic group by another. The following statement is typical of the archaeology of the period: "These two groups of hoards [in the British Late Bronze Age] may be taken to indicate first, definite invaders … and second, their fusion with the inhabitants and the absorption, modification, or discarding of their exotic types" (Kendrick and Hawkes, 1932: p. 135)

Despite the emphasis on invasions and migrations, individuals (who were presumably involved) were perceived as being passive spectators of the more important process. Hence Childe, when discussing the archaeology along the River Danube, could say, "whether these Moravian peasants actually came themselves up the Danube is immaterial; their culture did" (Childe, 1927: p. 85).

Culture history archaeologists viewed cultures or ethnic groups as organic beings, as living personalities. Their features were conceptualized like those of an individual. A culture was born, developed, and eventually declined, before moving on to another cycle of emergence, rise, and decay. The impact of these ideas is evident in the quasi-obsession with origins at that time, exemplified by such titles as *The Dawn of European Civilization* (Childe, 1925) and *The Beginnings of Egyptian Civilization* (Brunton, 1929).

In many ways, processual archaeology or New Archaeology continued some of the trends seen in culture history into the 1960s and 1970s (Jones, 1997: pp. 107–109; *see* Theory in Archaeology). The aim of processual archaeology was to develop methods for understanding the formation of the archaeological record and to refine approaches for inferring past behavior from observations of that record. This led to a growing interest in, for example, site formation processes (*see* Geoarchaeology), ethnoarcheology (*see* Ethnoarchaeology) and the use of analogy. There was thus an emphasis on the use of a rigorous hypotheticodeductive method (involving the testing of models and the use of inferential generalizations about the past). Within this perspective, culture was seen as a system of interrelated components (Binford, 1968: pp. 16–23). It was, however, to be criticized later, in the same way as functionalist anthropology (*see* Ethnicity: Anthropological Aspects), for its rather fixed views of human behavior.

As distinct from archaeology, the subjectivist or emic perspective for the study of ethnicity was increasingly being accepted in anthropology, at least from the 1970s (Jones, 1997). The general recognition of the role of perception in the definition of identity, and in particular of ethnicity, is partly a consequence of the influential work of Fredrik Barth. Barth (1969) radically changed the study of ethnicity with his proposal that ethnicity was something that could not be objectified, but that was defined by diagnostic socially relevant factors for membership and the (successful) ascription of the members to their ethnic group. Although he pointed out that all ethnic groups have their own overt signals (diacritical features that people look for and exhibit to show identity), together with basic value orientations (the standards of morality and excellence by which performance is judged), he considered that the critical features defining ethnicity were self-ascription and ascription by others, and that there was "no simple one-to-one relationship between ethnic units and cultural similarities and differences. The features that are taken into account are not the sum of 'objective' differences, but only those which the actors themselves regard as significant" (Barth, 1969: pp. 13–14). Barth's proposal ruled out the possibility of there being an objective and objectified way to designate ethnicity and use material culture as a critical factor in the study of ethnicity, and instead perception took on an essential role. Barth's ideas were later refined by other authors. Among them the work by Ronald Cohen should be emphasized. Cohen (1978) went even further than Barth when he stressed the situational and fluid nature of ethnicity, the influence of which was only possible as far as it was a meaningful element in social interaction. Although neither Barth nor Cohen, nor any of the other authors, arrived at the contention expressed above – that ethnic identity is multidimensional, and it is likely that multiple ethnic identifications coexist in the same person – Cohen (1978) almost reached this conclusion. Some of his examples clearly pointed in that direction. He even stated that "the same person can be categorized according to different criteria of

relevance in different situations" (Cohen, 1978: p. 388), but instead of conceding that more than one of these characterizations could be ethnic, he continued to consider ethnicity as monolithic.

Barth and Cohen were not dealing with prehistoric peoples, and never considered the issue of whether ethnicity was an appropriate concept to be applied to the past. There have been some claims that the concept is not applicable to precapitalist societies. Eriksen (1993: p. 80), for example, argued that outside Europe, ethnicity appeared only after peoples' contact with capitalism. There is some truth in this view, as some new ethnic groups were indeed created by colonizers (Cohen, 1978: p. 383; Gulliver, 1969: p. 15), or even by anthropologists (Cohen, 1978: pp. 380–383). However, colonizers seem to have created these new ethnic groups on the basis of preexisting ones, amalgamating, separating, or reorganizing them. This, rather than denying ethnicity's existence, demonstrates how ethnicity changes throughout time.

Colonizers may not have been successful in all their new creations, but in some they undoubtedly were. In the case of anthropologists (*see* Ethnicity: Anthropological Aspects), Cohen acknowledges that some of them had to provide a name for a 'tribe' (a concept that Cohen sees as equivalent to ethnic unit) "even when the group faded imperceptibly into other more or less similar named groups and was broken up into named subgroupings that had strong we/they feelings dividing them" (Cohen, 1978: p. 381). Following the definition of ethnicity provided above, one should interpret these anthropological categorizations on the one hand as reflecting the multiple levels of ethnic affiliation among these groups. On the other, they should be understood as an example of how anthropologists themselves used their own sense of a 'we/they' division in order to classify 'the other' in their own (nationalistic) language. Their nationalistic perspective would lead them to deny all groupings as ethnic and hence to the need to decide which of them was the only one – the proto-ethno-nation – that should be considered as their object of study. As indicated above, nationalism has left a definite mark on the way ethnicity has been understood, mainly with respect to its one-dimensional characterization.

In archaeology, the first major break with the processual paradigm did not occur until the early 1980s, much later than in anthropology (*see* Ethnicity: Anthropological Aspects), to which it was clearly related. The seminal book in this process was Ian Hodder's *Symbols in Action* (Hodder, 1982b), which was, not coincidentally, an ethnoarchaeological study (*see* Ethnoarchaeology). Hodder depicted the manipulation of material culture by several groups in East Africa as active in creating social relationships, and stressed the need to find ways of interpreting the meaning(s) of material culture. Wider discussions of this topic were, however, well underway by then, as shown by many of the contributions to *Symbolic and Structural Archaeology* (Hodder, 1982a). The major aim of this body of research was the study of living cultures "in order to shed some light on the analysis and interpretation of cultures in prehistoric archaeology"(Hodder, 1982a: p. 1). Interestingly, Hodder's ethnoarchaeological work originated from an overtly processual hypothesis, which was to test the relationship between resources, interaction, and cultural similarity (1982a: p. 8), and it was assumed that cultural similarity would 'reflect' degrees of interaction (Hodder, 1982a: p. 9). However, observations made during Hodder's ethnographic fieldwork showed that while the use and distribution of certain items such as drinking cups, wooden eating bowls and stools followed the expected patterns, those of other items, such as spears and calabashes, did not. Hodder concluded that "the extent to which cultural similarity relates, for example, to interaction, depends on the strategies and intentions of the interacting groups and how they use, manipulate and negotiate material symbols as part of those strategies" (Hodder, 1982a: p. 185). These interacting groups were ethnic (tribal), but other subgroups within those societies, such as younger men and women, were also seen to follow their own strategies in their relations with the dominant older men.

Despite Hodder's important contribution on ethnicity, for several years archaeology remained reluctant to analyze this issue of ethnic identity. In 1989, Shennan published a much-cited article in this area, but in it he referred mainly to culture instead of ethnicity (Shennan, 1989). This was not the case in the Polish journal, *Archaeologia Polona*, which in 1991 dedicated an entire issue to ethnicity and archaeology. The articles published here, together with others that have subsequently appeared (e.g., Díaz-Andreu, 1998; Dietler, 1994; Funari, 1999), show that the debate was becoming more intense. This process was further fostered by the 1997 publication of Siân Jones's book, *The Archaeology of Ethnicity*, which provides archaeologists with an excellent overview of the state of the debate. In the last few years, many archaeologists have continued discussing ethnicity in archaeology (Bawden and Reycraft, 2009; Curta, 2005; Di Hu, 2013; Levy, 2008; Lucy, 2005; Stojanowski, 2010; Weik, 2009).

Abstract

Immigrants do not fare as well as natives in economic terms; even after including many controls, an unexplained part remains. The ethnic identity entered the field of labor and migration economics in an effort to better explain the economic outcomes of immigrants, their behavior, and their often perceived as irrational and suboptimal choices. Quantifying ethnic identity is a major issue; even more challenging is to measure its impact on economic outcomes such as the probability to work or the earnings of immigrants. The thin but burgeoning theoretical and empirical literature shows that ethnic identity has a significant impact on the economic behavior of immigrants.

Introduction

The Greek and Latin etymology of the words ethnic and identity shows that these concepts exist among humans for at least 2000 years. Ethnic is derived from the Greek word *ethnos* that means nation, people, caste, and tribe. It is akin to the Greek word *ēthos* that refers to the spirit, customs, beliefs, and aspirations of a group. The word identity comes from the Latin *identitas* and *idem* and denotes the concept of sameness and oneness. Together they define the notion of a person's individuality and self-recognition, as a person is part of and shares the culture of a larger group. Together, they emphasize boundaries and juxtaposition to the otherness. While reference groups become essential in ethnic identity formation and adaptation, bloodlines are not so relevant.

Social scientists have long understood the importance of ethnic identity as it shapes people's lives individually and within a society and a country. Social psychologists, sociologists, anthropologists, historians and economic sociologists, and political scientists have been studying ethnic identity for decades in social, sociopolitical, psychological, and educational contexts. However, the construct entered the realm of economics and became the subject of in-depth studies only recently. Quantifying the concept of ethnic identity is a major issue. The nonavailability of data, endogeneity issues, selection biases, and inadequate theoretical frameworks have been some of the hurdles economists face.

Studying ethnic identity and its impact on the labor market is of outmost importance; it can offer key insights to the economic outcomes of immigrants in the host country, and suggestions to an effective migration policy that caters to needs of immigrants and encourages their integration. Other social phenomena such as ethnic diversity, multiculturism, ethnic mobilization, diaspora effects, ethnic uprising, minority issues, intercultural dialogue, national identity, etc., make more sense after we understand ethnic identity.

Ethnic identity as a concept, its meaning, and use in economics is presented in Part 1. The theoretical considerations and empirical advancements in measuring ethnic identity are offered in Part 2. How attached people are to their ethnic group and see themselves compared to the majority identity can influence their labor market decisions. Part 3 elaborates how these aspects of ethnic identity relates to choices of participating in the labor force, working in the primary labor market, using social networks to look for a job, employment level (prestige), as well as wage. Finally the conclusion summarizes.

Ethnic Identity as a Concept

The definition of ethnic identity is crucial when one wants to build a theory and provide an analytical framework to evaluate the impact of ethnic identity on economic phenomena. There is no specific definition of ethnic identity in economics. Researchers use common definitions of the words – as they are defined in dictionaries and in other sciences – and often adapt them to their specific study.

Identity is interconnected to the perception individuals have about themselves, their being and their role in society; it is their distinguishing character that includes both the physical appearance and the sense of belonging or not to a group. It is what makes individuals unique and different from others and it is self-defined. It denotes how strongly an individual is attached, relates, or feels a sense of belonging to a particular ethnic group or culture. It signifies a sense of continuity of belonging to a group that shares certain elements such as cultural practices, language, interactions with society and ethnic peers, as well as preferences for same-ethnic friends or colleagues. The ethnic identity of individuals describes their social, psychological, and consumer behavior (Constant et al., 2006b). In contrast to ethnicity, or ancestry, which is a permanent characteristic and externally identifiable, ethnic identity can continuously morph throughout a person's life. It can change or develop due to age, relationships, experience with others, discrimination, religious influence, time, and migration, among a number of other factors. But since it can change and requires self-assessment, it is challenging to capture and measure it in a way to allow for comparisons or evaluations.

As sociologists have shown, ethnic or racial identity can alter when conflicts arise; they distinguish the concepts of situational ethnicity and opposing identity. In the US, segregated neighborhoods can create the structural conditions for the development of 'an oppositional culture that devalues work, schooling, and marriage' and impedes success in the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.94005-4

larger economy (Massey and Denton, 1993). If ethnic identity varies from that of most people in a country, it can also be defined as the minority, or 'oppositional,' identity, which simply indicates that it is outside the majority, or dominant, identity in society. Battu et al. (2007) find that nonwhites choose to adopt 'oppositional' identities; some individuals may identify with the dominant culture and others may reject it, even if it implies adverse labor market outcomes. More recently, Mason and Matella (2014) using self-identification as white as a measure of acculturation and the fraction of all hate crimes directed at Muslims as a measure of stigmatization show that after 11 September in the US, there was a statistically significant and substantively large decrease in the probability that Arab and Islamic Americans will self-identify as white.

When individuals live in their home country are part of the majority (There are some exceptions such as the Jews, who are a minority in other countries and become a majority when they migrate to Israel.) and their ethnic identity is not in conflict or contrast with others. However, when people move to a new country, they immediately feel the clash of cultures. The contrast of cultures, languages, mores, and customs poses a polylemma. An immigrant ponders whether to keep their identity and remain true to their origins, to shed all ancestral attachments and adopt the new culture, or to find some combination of both. Ethnic identity applies to natives as well. By being in contact with immigrants and their culture, natives can also alter their own identity. This additional complication of moving identities makes the measurement of ethnic identity all the more difficult. The ethnic identity of immigrants – the attachment to the culture, language, traditions, etc., of the home country – can be further challenged, changed, or redefined based on their experiences with additional years in the host society, particularly if they face discrimination or acceptance. How people perceive and interpret their surroundings result in a personal and individual adaptation (Phinney et al., 2001). Ethnic identity may or may not influence an individual's other identities such as national identity – how attached a person feels to his/her country. But it has been found that religion is a decisive factor for ethnic identity evolution (Constant et al., 2009).

The way natives receive immigrants, their attitudes, and perceptions about immigrants can trigger different ethnic identity reactions among immigrants. If immigrants switch identities because natives treat them differently, this may very well result in different economic integration patterns. In a theoretical and empirical study, Manning and Roy (2010) examine how people see others and how they see themselves. They focus on the cultural assimilation of immigrants in the UK, the British identity and rights and responsibilities in societies. They find that while almost all UK-born immigrants identify as British, and the rest feels more British with additional stay in the UK, the white UK-born population does not perceive these immigrants as British. Interestingly, they are worried that Pakistanis who feel British are causing problems but are not worried about Italians who do not feel British and cause problems.

How to Measure Ethnic Identity

Ethnic identity becomes all the more salient in economics. Akerlof and Kranton (2000) helped increase discourse about the role of identity in economics. A strand of literature is developing that places identity, behavior, and personality traits in the heart of labor markets and the performance of individuals. The general goal is to explain economic labor market integration and unexplained wage differentials whether examining sex, racial, minority, or immigrant-native differences.

Theoretical Advancements

Once the concepts of one's identity, personality, and well-being entered the utility function of the individual agent and became part of modern economics, researchers showed that these concepts significantly affect economic behavior and can even explain 'irrational' and suboptimal choices and outcomes. Akerlof and Kranton (2010) demonstrated that when facing economic decisions, including those in the labor market, people choose different paths, even when given the same incentives; the missing explaining link is identity. The ethnic identity and its significance in economic behavior triggered new research in labor and migration economics. How a person sees himself or herself compared to others and fitting into a larger group (i.e., the ethnic community or society at large) can lead to nonrational economic outcomes (Constant and Zimmermann, 2011).

Akerlof and Kranton (2000) offer a novel theoretical framework of the utility maximization function and a more realistic economic rigor to neoclassical economics. They conceive a person's self-identification as powerful motivation for behavior, implying that achieving an 'ideal self' and being comfortable with one's identity is bound to affect one's utility function. In this case, utility increases; otherwise, utility decreases. Accordingly, even rational individuals may reach nonoptimal solutions if they cogitate about their identity.

Incorporating a broad class of beliefs including identity, Bénabou and Tirole (2011) developed a model that can explain labor market integration and wage differentials. The authors also examine self-serving beliefs linked to pride, dignity, or wishful thinking that arise endogenously. For example, some individuals may have the human capital and the drive to integrate and flourish in the labor market, but they may not succeed because their behavioral norms are in the way and their self-identity images are muddled.

To explain the evolution of behavioral ethnic codes that people follow in order to maintain social acceptance, Kuran (1998) created a theory of reputational cascades; they can explain why similar societies may exhibit different levels of ethnic activity. The theory incorporates the speed of acting ethnic, chosen under social pressures, which in turn the individuals themselves create and sustain; interdependencies among individual incentives are strong and crucially affect personal choices. Darity et al. (2006) developed a long-term theory of racial (or ethnic) identification formation. In this evolutionary game theory model, there allow for multiple equilibria; one, in which everybody follows an individualist identity strategy, another in which everybody pursues a racialist (or ethnic) identity strategy, and yet another equilibrium as a mixture of both. Accordingly, race or ethnicity may be more or less significant for both market and nonmarket social interactions. The foundation of this theory is the positive impact of racial identity on the productivity of

social interactions, which also explicates the persistence of racial or ethnic advantages in market economies.

The Ethnosizer

As mentioned, one barrier to more thorough economic studies was measuring ethnic identity in order for comparison. A breakthrough came with the 'ethnosizer,' a measure of the intensity of a person's ethnic identity (Constant et al., 2006b). The authors conceived and defined ethnic identity as the balance between the commitment to or self-identification with the culture and society of the country of origin and the host country. With the ethnosizer, they offer a complete concept of ethnic identity and a new approach for empirical modeling.

The ethnosizer can be one-dimensional, two-dimensional, or multidimensional to capture the dynamic and multidimensional character of ethnic identity. The authors allow the ethnosizer to differ among immigrants of the same origin, and/or be comparable among immigrants of different ethnic backgrounds. The one-dimensional ethnosizer in which ethnic identities toward the home and host country are mutually exclusive, it is very much related to the assimilation literature. It assumes that every time a person becomes more assimilated toward the host country he/she has to become less attached toward the home country. This can be visualized by drawing the Cartesian plane and focusing on the upper right quadrant, in which the horizontal axis measures commitment to the home country and the vertical axis measures commitment to the host country. The line that connects the two axes (the hypotenuse in Figure 1) illustrates how immigrants alter their ethnic identity; it is the one-dimensional ethnosizer.

Constant et al. (2006b, 2009), (These states mirror Phinney et al.'s (2001) four acculturation strategies in the psychology field, built off of previous acculturation theory (Berry, 1980).) created the two-dimensional ethnosizer that allows for more realistic possibilities of the ethnic identity of immigrants such as the simultaneous commitment to both countries and other permutations. The ethnosizer is based on five elements that best capture the essence of ethnic identity: language, culture, societal interaction, history of migration, and ethnic self-identification. (Zimmermann et al. (2007a) compared the ethnosizer to the ethnic self-identification measured directly from the German Socio-Economic Panel (GSOEP) and showed that the ethnosizer is a better measure of identity.) As in the one-dimensional ethnosizer, the horizontal axis measures the commitment to the home country and culture and the vertical axis commitment to the host country and culture with respect to the five elements. In this case, immigrants are allowed to traverse through the space defined by the box that the axes can form. This box identifies four distinct states of ethnic identity, differentiated by the strength of commitments to each country. (1) Assimilation: a prominent identification with the host culture and society, a firm conformity to the norms, values, and codes of conduct, and a weak identification with the origin. (2) Integration: a simultaneous dedication to and identification with the ancestral and the host society. This is a state of biculturalism. (3) Marginalization: a pronounced detachment from either the dominant culture or the culture of origin. (4) Separation: a strong commitment to the culture of origin even after years of emigration, along with weak involvement in the host culture and country realities. A migrant can undergo a more intricate journey through the four states. An

Figure 1 Complete illustration of ethnic identity; retention, relinquishment, and subversion. Reproduced from Constant, A.F., Zimmermann, K.F., 2008. Measuring ethnic identity and its impact on economic behavior. Journal of the European Economic Association 6 (2–3), 424–433.

interesting aspect of the ethnosizer is that in what state individuals end up varies among immigrants even from the same country.

Figure 1 illustrates how Constant and Zimmermann (2008) expanded the theoretical possibilities of the ethnosizer by allowing the commitments to the countries to become negative, thus taking into consideration the multidimensionality of ethnic identity. Accordingly, ethnic identity includes the extreme cases of 'subvert,' negative, or undermining manifestation of ethnic identity. Using the same setting of the Cartesian coordinates, a migrant can move from the upper right quadrant to the lower right or the upper left or the lower left. Moving to the right along the positive part of the horizontal axis expresses ethnic retention and increasing commitment to the country of origin. Point (1,0) shows maximum commitment to and self-identification with the culture of origin and zero commitment to the host country. It is possible that immigrants move beyond point (1,0), as they identify more fanatically with the country of origin. For example, this is the case of radical individuals practicing more extreme views than even comparable coethnics who stay in the country of origin. The ethnic identity can also manifest along the negative part of the horizontal vector indicating that immigrants turn against their own heritage and culture.

Moving up from (0,0) to (0,1) on the positive vector of the vertical axis, indicates increasing identification with the host country to the point of reaching maximum assimilation. The ethnic identity of immigrants can move beyond point (0,1); such is the case of overzealous migrants, who identify with the host country even more than comparable natives. Another possibility is that immigrants actively resent the host culture and develop a subvert self-identification toward it. This is illustrated by the movement on the negative vector of the vertical axis. The lower right quadrant characterizes individuals who keep the ancestral identity, but turn against the host country. In the lower right quadrant, individuals are turning against both countries.

Epstein and Heizler (2015) provide a theoretical framework that sheds light on the ethnosizer literature. In their theoretical model of utility maximization, they incorporate ethnic identity and add a time dimension. They show that two identical migrants arriving at two different periods will have a different the ethnic identification, which will increase over time.

Empirical Advancements

Measuring and quantifying ethnic identity is a difficult task. This intrigues economists, yet generally speaking the field of economics has been unhurried to undertake thorough research on ethnic identity, mainly due to endogeneity issues and sample biases (Constant and Zimmermann, 2013). Do individuals accept work opportunities and make decisions because of their ethnic identity, or do people's identities define their work opportunities? These questions reveal the endogeneity problem. Empirically, endogeneity and sample bias are additionally affected by the fact that respondents are self-evaluating and self-reporting their ethnic attachment making it difficult to prove causality.

Another dimension of the difficulty is lack of data that contain appropriate information about ethnic self-identification and attachment to the home or host country. There are some exceptions such as the Ethnic Diversity Survey in Canada, the British Household Panel, or the GSOEP. Lastly, it is difficult to effectively and quantitatively distinguish between discrimination and an individual's own ethnic choices or preferences; this holds true for many tastes or preferences, as well as for ethnic identity influencing one's employment choices.

Utilizing the GSOEP waves 2000–02, and combining information of the five elements that compose the ethnic identity, Constant et al. (2006b, 2009) created the two-dimensional ethnosizer. The measure ranges from zero, indicating full commitment to the host country, to one indicating full commitment to the country of origin. The authors find that men are closer to the native German ethnicity than women due to greater language use and cultural aspects attachment but the gender difference is not significant. They also find that young migrants are integrated and assimilated the most; immigrants with higher education or college degrees (from the home country) integrate, but do not assimilate. Regarding the ethnicities of immigrants in Germany, the authors show that ex-Yugoslavs assimilate more and separate less than Turks, but they also marginalize more. While Greeks, Spaniards, and Italians were no different than Turks, other ethnicities integrated and assimilated more. The results from the ethnosizer are mostly influenced by premigration characteristics; making this measure exogenous to the economic and social processes that immigrants experience in Germany (Zimmermann, 2007). (Hochman and Davidov (2014) used the GSOEP and found that it is German language proficiency that has a strong impact on the national identification of immigrants and not the other way around.)

Georgiadis and Manning (2013) studied the correlates of national identity in Great Britain and showed that these people who feel they are well treated and tolerated with their values are more likely to identify with the country and have feelings of belonging to society. Also, individuals who live around their likes have a stronger feeling that they too belong to the country.

Below, I focus on labor market outcomes, specifically individual decisions to work, how many hours to work, the use of informal ethnic networks to look for work, as well as employment and wages.

Ethnic Identity and the Labor Market

Some empirical economists embarked upon the quest to improve human capital models and gain a greater understanding of the behavioral determinants of occupational and monetary success by utilizing ethnic identity. The question is whether ethnic identity matters and is useful to immigrants and natives. The rationale is that immigrants are mostly useful in the host country when they possess different talents and skills than natives, and when they bring with them characteristics that are relatively scarce. This improves labor market efficiency. When a population is homogeneous, there is always the risk of lost creativity. There are, however, costs and benefits associated with this cultural capital embodied in immigrants. When

immigrants and natives are complements to each other, both can profit as well as the economy and society can benefit from creativity, dynamism, and greater prosperity. Most of the empirical studies and findings are based on cross-sectional evidence and on a few countries.

When nonwhites in the UK identify with their social environment, their culture of origin, and when social networks assist them in finding jobs – they end up with totally different choices than other otherwise identical individuals (Battu et al., 2007). On the other hand, Battu and Zenou (2010) show that social environment influences the individuals' identity choice. Those nonwhite British who develop and manifest oppositional and extreme identities are penalized in the labor market, facing a 6–7% lower probability of being employed.

Linking identities, conflicting behavioral norms, and job attributes, Russo and van Hooft (2009) find that individuals who experience conflicting norms in the labor market choose job characteristics that can reduce the degree of conflict such as favorable working hours and good relationships with colleagues and managers. While men favor a career when a conflict between career and leisure arises, women do not. Bisin et al. (2011) find that in European countries, immigrants face more difficulties to enter the labor market than natives do. Across all levels of education, those with strong ethnic identities experience a penalty in the labor market. The authors suggest that more flexible labor markets can ease these difficulties for immigrants, but not those with strong ethnic identities. In contrast, in Sweden, income and employment differences for foreign-born men depend on the strength of the *majority* identity, irrespective of ethnic identity (Nekby and Rödin, 2007).

Constant et al. (2006a) studied the effect of ethnic identification on the probability of working in Germany by sex. The probability of immigrant men working is not affected when they are integrated. The probability of working for immigrant women, on the other hand, is significantly affected if they are integrated. Constant and Zimmermann (2009) extend the ethnosizer framework to model labor force participation and earnings disaggregated by sex. They find that the ethnic identity of immigrants in Germany is a strong determinant of their labor force participation. Interesting gender dynamics show that immigrants (both men and women) who are separated and marginalized are less likely to work than those who are assimilated and demonstrate a strong commitment to the German society. In addition, women who were integrated tended to work more than those who were assimilated, but there was no significant difference between integrated men and assimilated women. Curiously, they find that ethnic identity does not significantly affect the earnings of men and women workers. They explain this finding through the selection process in the labor market. In other words, ethnic identity can make a difference in the probability to work, but once immigrants have a job, their ethnic identity does not affect their earnings.

Applying the ethnosizer on different data in Germany – the evaluation data set on the unemployed – Constant et al. (2011) demonstrated that those unemployed immigrants who are separated experience a relatively slow reintegration into the labor market.

Job Search and Working in Ethnic Enclaves or the Primary Market

Identity within an enclave or ethnic group shapes an individual's decisions regarding work. Being part of an informal network can have positive and negative effects on employment and wages. An individual may have access to information and job opportunities within their ethnic group thus more likely to find a job through their network. Benefits could include work that aligns with ethnic practices or religious beliefs. Repercussions may be that the job offers a wage below her human capital capabilities or is outside of the primary labor market. Further, the individual may be stuck in the enclave and never be able to access the entire labor market possibilities. Ethnic identity can influence the decision to enter the primary labor market (labor force participation). More opportunities, along with pressure, encouragement, or willingness to economically assimilate may drive an individual to and work with the majority population, as opposed to working in the enclave. It is also possible that an individual combines both markets such as a medical doctor who works in the primary market, but because of his/her ethnic advantage in language for example, can also have coethnic patients and an expanded clientele.

Pendakur and Pendakur (2005) find that some individuals in Canada desire to work among coethnics and thus are willing to 'pay' for it through accepting traditionally classified low-quality jobs but that are within the ethnic enclave. Regarding job search, the authors find almost 40% found their current job through an informal network, including family and friends. A study on ethnic identity and employment in the US finds that ethnic minorities prefer to have same-race friends despite the economic gains of having white (in this case the majority group) friends, who open social networks in the mainstream labor market (Battu et al., 2007). Choosing to conform to the 'white's norm' depends on peer pressure, offered wages, and the impact on the minority unemployment rate (Battu et al., 2007). This delicate balance between outsiders' perceptions versus those of an individual is demonstrated again in Canada through examining 'visible minorities'; those with strong ethnic identity work jobs with lower occupational prestige than visible minorities without deep ethnic identity (Pendakur and Pendakur, 2005).

Therefore depending on the strength of individuals' ethnic identity, behavioral decisions will be based on a trade-off between expected social and economic outcomes. It seems likely that a person who strongly identifies with her ethnicity could favor social networks to find a job or work in the ethnic economy, despite it possibly being a suboptimal economic decision, since she gains social reassurance and benefits which she may personally value more than additional employment prestige or salary.

An individual's attachment to his ethnic group can affect the decision to work, the (un)employment rate, choosing to work in the primary or ethnic economy, the level (prestige or quality) of his job, and if employment aligns with his human capital. A study on ethnic minorities in England finds that nonwhites adopting an oppositional identity (i.e., strong ethnic identity) experience higher unemployment and low probabilities of finding a job compared to "other non-whites who choose to adopt the white's norm" (Battu and Zenou, 2010; similarly to

Mason's (2004) research showing wage differences depending on ethnic identity). The authors also show that there is a lower probability of being employed (6–7% lower) for those with 'extreme identities.' This is a smaller effect than domestic educational qualifications, interethnic marriage, and home and car-ownership, yet a larger effect than language fluency and ethnic enclaves (Battu and Zenou, 2010; Mason, 2004).

As stated, there are benefits to working in the ethnic economy, but it has been found that participation in it also lowers social activities in the overarching society, creating a social cost (Fong and Ooka, 2002). It is possible that working in the ethnic economy also has economic costs, as it may not efficiently utilize human capital or may offer a lower wage than the primary labor market. For example, an individual may work a job involving the production or sale of ethnic goods, perhaps in an ethnic restaurant, market, or clothing store because she has the necessary language and ethnic know how despite also being overeducated for the position. On the other hand, she may willingly accept, or even prefer, this job since it may offer social benefits or lowers her economic risk.

The trade-off between economic gains and 'social reassurance' exemplifies why seemingly economically irrational behavior may actually be rational for the individual (Akerlof and Kranton, 2000; Pendakur and Pendakur, 2005: p. 2). It also demonstrates the reality that traditional economic measurements for employment level or prestige – such as earnings – are no longer always the appropriate tools to evaluate labor market outcomes. Attempting to include personal utility stemming from ethnic community payoffs seems to be integral for economists to include in analyses.

Wages

Ethnic identity may have direct effects on an individual's wage, which could be surprising if one had assumed wage differences stemmed from how *others* perceive the individual. But Mason (2004) shows that Mexican- and Cuban-Americans were able to increase their income and hourly wages by 'acculturating into a non-Hispanic white racial identity' (although it was not enough to overcome penalties for those with a dark complexion). Acculturation is similar to ethnic identity, as seen above, in the sense that an individual decides how attached she is to a culture or ethnic group. If a person self-reports a low ethnic identity (weak attachment) and identifies more with the majority identity, it can result in higher economic gains than peers with a high ethnic identity (Mason, 2004), particularly if she interacts with the majority and has access to the primary labor market.

Studying the effect of ethnic identification on income, Zimmermann (2007) applied the two-dimensional ethnosizer and showed that integrated men and women experience a dramatic earnings growth; the increase in the earnings of women is higher. Full separation and full marginalization led to a decrease in labor earnings for both male and female migrants. Using the ethnosizer and Greek data, Drydakis (2012) found that assimilation and integration significantly increase the wages of immigrants; separation and marginalization decrease them. More recently, Gorinas (2014) extended the *ethnosizer* by developing *the modernization index* to measure openness to majority norms. He showed that while immigrant employment in general is almost unaffected by the ethnic identity of immigrants in Denmark, immigrant women benefit from significantly better employment outcomes.

Endogeneity Issues

Experiments offer a way to circumvent the endogeneity issue. Following social psychology methods to introduce an exogenous variation in identity, Benjamin et al. (2010), could identify the marginal effect of a particular social category by priming subjects as respondents – temporarily – lean toward the norms associated with the salient category. That is, the authors prime identities with unknown norms and can infer what those norms are through the behavioral response to the prime.

Conclusion

How a person's multifaceted identities mix, conflict, or reinforce each other has been and continues to be an interesting research topic across the social sciences and an important point for public policy, including immigration policy. Varying levels of ethnic identity have social benefits to enrich a country's overall society and culture, as well as economic benefits since those with strong attachments to an ethnic group can possess different human capital and skills than the majority identity. At issue is whether immigrants should assimilate, or integrate in the host country. Likewise economic migrants are willing to move abroad, but how willing or likely are they to adopt the host country's culture and societal norms? Migrants become assimilated, integrated, marginalized, or separated into society (the four states of the ethnosizer), which can directly impact their labor market outcomes.

Competing directly with natives and no longer having any culture-specific human capital as an additional qualification is not advantageous for immigrants. At the same time, preserving one's ethnic identity with dignity and pride is important, and integration can be enriching and rewarding for immigrants.

Research thus far has shown a strong impact of ethnic identity on the labor market. Some individuals can avoid the labor market penalties through relinquishing their ethnic identity and showing greater attachment to the majority, or dominant, identity (i.e., stronger assimilation); although those with certain factors – such as dark complexion – may be unable to do so. Economic gains may rise with increased interaction with the majority population since these connections can open new opportunities in the primary labor market and individuals may experience less discrimination. These interactions help to explain why second-generation immigrants show greater economic assimilation.

Of those self-assessed of having an ethnic identity in Canada, about 40% found their current job through an informal social network, which demonstrates the usefulness of extracting information from the ethnic group and benefiting from labor market outcomes. For those working, jobs may be in the ethnic economy rather than in the primary labor market. These positions carry a trade-off between economic gains and

social benefits (within the ethnic group) that is slowly being understood and captured in data.

Decisions to work, pay taxes, and employment levels and prestige all influence the nation's productivity, efficiency, and output. Hence immigrants' ethnic identity is a public policy topic. It is improbable that a country would aim to marginalize people based on ethnic identity, likewise it is unusual that individuals are separated from both home and host cultures. If a nation's objective is to have assimilated migrants, then giving preference to young migrants with degrees is a strong approach to immigration policy (Constant et al., 2006a,b). If a country decides that national identity is more important, they can create policy to encourage assimilation and for group to feel accepted, which makes it more likely that national identity will be strong (Phinney et al., 2001).

The two-dimensional ethnosizer depends on premigration characteristics, and is exogenous to economic activity. Postmigration variables play practically no role in explaining the *de facto* exogeneity of the ethnosizer variables found in the literature.

Abstract

This article provides an overview of the definitions, development, and key correlates of ethnic identity. Ethnic and multiple identities are discussed primarily from the perspective of social and acculturation psychology, which traditionally employ a sociocognitive approach. In addition, a discursive approach to these phenomena is presented and discussed. Ethnicity is a matter of subjective belief in common ancestry but individuals use different criteria for defining their ethnic identity to construct it situationally. In this article, different theories, methodologies, and single studies on ethnic identity and intergroup relations are linked to individual, interactive, and societal levels of analysis.

Defining Ethnic Identity

Ethnic identity will here be discussed primarily from the perspective of social, acculturation, and discursive psychology. Before that, two major concepts are discussed, ethnicity and identity, as they have been given numerous different definitions within the social sciences.

The term 'ethnicity' has its roots primarily in anthropology and ethnology. Ethnicity refers to a sense of belonging to a particular (assumed) ancestry and origin (Liebkind, 2006). An ethnic group is thought to exist whenever the belief in common descent is used to bind people together to some degree. This sense of origin is often accomplished by defining ethnicity in terms of metaphors of kinship: ethnicity is family writ large. What makes an ethnic group specific is this genealogical dimension. While ethnic group is sometimes used to refer only to those in less powerful positions, ethnicity refers to everybody; all people are members of (at least) one ethnic group, although ethnic group membership has more often been studied in minority than in majority groups. The majority/minority distinction has also been criticized, not least because it tends to confound relative group size with status or power. However, within social psychology, this distinction is widely used, acknowledging that numerical asymmetries often, although not necessarily, coincide with status or power asymmetries.

Even though identity has the reputation of being one of the slipperiest concepts in the social scientist's lexicon, it can be fruitful in conceptualizing ways in which people conceive themselves and are characterized by others. Identity is all about the intricacies, dilemmas, contradictions, and imperatives of the relationship between individuals and their social environment (Verkuyten, 2005). People's identities can be seen to have two components, personal identity and social identity, and the latter derives from the recognition of and value attached to membership in various groups (Tajfel, 1981). Research on self-awareness shows that people can distinguish personal from social identity and that the momentary dominance of one or the other depends on the situation and shapes behavior.

Ethnicity is often seen as an essential part of identity, but the salience of ethnicity varies situationally as well as during the lifetime of an individual. Ethnic identity refers to an individual's sense of self in terms of membership in a particular ethnic group. Although ethnic identity is sometimes used to refer simply to one's self-label or group affiliation, it is generally seen as embracing various aspects, such as self-identification, feelings of belongingness and commitment to a group, a sense of shared values, and attitudes toward one's own ethnic group (Liebkind, 2006).

Ethnic identity differs from other social identities because ethnicity is a matter of subjective belief in common ancestry. The notion of where one came from provides people with an important sense of an enduring identity and feelings of connectedness (Verkuyten, 2005). Different criteria such as physical similarities, cultural characteristics, language, religion, and historical events and myths can all play a role in the definition and justification of a common origin. However, ethnic identity is not necessarily tied to culture: a sense of ethnic identity can remain strong, although cultural changes take place (Verkuyten, 2005).

Subjective beliefs in common origin, descent, and history are socially constructed and therefore always subject to reinterpretations, adjustments, and change. As all social identities depend crucially on acknowledgement and acceptance by others, also ethnic identity is sustainable to the extent that it is expressed and affirmed in social interaction (Verkuyten, 2005). However, although ethnic identities are malleable, they are not complete fabrications. A person's ethnicity is ascribed in the sense that one cannot choose the ethnic group into which one is born, but it is achieved to the extent that the meaning it acquires for one's total identity can be a matter of choice. The fact is that the ascribed aspect of ethnicity can be played down to the extent that ethnic identity is made equal to other social identities, but transmitted as it is in primary socialization, ethnicity is often a relatively pervasive part of identity (Liebkind, 2006).

Levels of Analysis in and Different Perspectives on the Study of Ethnic Identity

Three levels of analysis have typically been distinguished in the study of ethnic identity: individual, interactive, and societal. The first level involves intraindividual (psychological)

processes and personal characteristics, and the focus can be, for example, on pride in and identification with one's ethnic group. The second level is the level of interaction and it refers to the dynamics of everyday contacts in different situations. The emphasis is here on the emergence and maintenance of ethnic identity in situated interaction and ethnic identity is examined in terms of an ongoing process of social definitions and negotiations. The first and second levels are the ones most often studied by social psychologists. The third level of analysis is the societal level and it is made up of political, ideological, cultural, and economic features. Here, ethnic identity is investigated, for example, in relation to legislation, dominant discourses, and the power and status differences between ethnic groups. Social psychologists frequently take also this level into account when studying ethnic identity, then often focusing specifically on intergroup relations and how they are affected by prevailing intergroup attitudes in society. The level of interaction mediates between the other two; it is in interactions that societal relations, beliefs, norms, and values are reproduced, changed, or challenged, and it is in interactions that a sense of self and ethnic identity is formed. Through these interactions, the institutionalized practices, group statuses, and labels affect the way people define and position themselves. Simultaneously, people can challenge and respond to these social structures and expectations, and actively struggle to establish and affirm their own sense of ethnic identity in interactions (Verkuyten, 2005). The emergent and changing qualities of ethnic identity thus coexist with people's relatively stable sense of their self.

There are many different theoretical and methodological approaches to the study of ethnic identity. One approach can be described as sociocognitive, and it informs us about the cognitive, evaluative, and emotional dimensions of ethnic identity (e.g., Social Identity Theory, Tajfel, 1981). Within acculturation psychology, ethnic identity is perceived to be that aspect of acculturation, which concerns the subjective sense of belonging to a group or culture, while acculturation is a broader construct, encompassing a wide range of behaviors, attitudes, and values that change with contact between cultures (Phinney et al., 2001). A third perspective is that of discursive psychology and it contributes to the understanding of identities as contextually and interactionally constructed and negotiated phenomena (e.g., Verkuyten and de Wolf, 2002). These general perspectives complement each other and offer together a broad understanding of ethnic identity. Next, the development of ethnic identity will be briefly discussed, followed by some examples of research on ethnic identity and intergroup relations within the acculturative and other sociocognitive approaches and, finally, discursive approaches.

The Development of Ethnic Identity

Traditionally, ethnic identity development has been treated as part of a broader process of linear development. In this perspective, an ethnic identity is developed and modified as children become aware of other groups and of the cultural/ethnic differences between themselves and others, and attempt to understand the meaning of their ethnicity within the larger setting.

According to the stage model of ethnic identity, developed in the United States by Jean Phinney (1989), ethnic identity begins in a rudimentary form in childhood and remains largely unexamined; that is, children have not thought through for themselves the meaning of their ethnic group membership. Ethnic identity becomes especially central during adolescence when ethnic minority adolescents must negotiate the identity formation process in terms of interpersonal relationships and occupation as well as contend with their minority group status within the majority culture and define how this aspect of their identity informs who they are and who they will become. The optimal outcome of the ethnic identity formation process during childhood and adolescence is the achievement of a secure and confident sense of one's ethnic group memberships. Through the joint processes of exploration and commitment, individuals are expected to move in adolescence from ethnic identity diffusion (lack of a clear identity) to either foreclosure (a commitment without exploration) or moratorium (a period of exploration) and to ethnic identity achievement, involving a firm commitment to one's ethnic group(s) based on an exploration that has led to a clear understanding of ethnicity. By adulthood, most people have acquired a relatively stable and secure sense of themselves as ethnic group members, that is, an achieved ethnic identity (Phinney and Ong, 2007). Although ethnic identity formation has been mainly considered as a major developmental task of adolescence, the process may continue in cycles that involve further exploration or rethinking of the meaning of one's ethnicity.

The development of ethnic identity does not happen in a social vacuum; social identities, intergroup attitudes, and interactions influence each other reciprocally. Social identity processes have implications for intergroup relations because one has a need for a positive self-concept and, as a consequence, there will be bias in social comparisons with other groups to look for ways in which one's own group can be favorably distinguished from other groups (Tajfel, 1981). This group-serving tendency – intergroup bias – can take the form of favoring one's in-group and/or derogating out-groups and sometimes the strength of identification with one's in-group correlates positively with in-group favoritism and/or out-group derogation (e.g., Hodson et al., 2003). However, others assume a negative relationship between in-group identification and in-group favoritism and/or out-group derogation; research on ethnic identity development in adolescents and young adults suggests that strong ethnic identities constitute markers of maturity, consideration of intergroup differences, and are ultimately associated with less intergroup bias (e.g., Wittig, 2008). Thus, a strong ethnic identification among minority members may in some contexts imply positive and in other negative attitudes toward the national out-group.

These mixed results may be due to substantial differences in the ways ethnic identity is measured. Besides the cognitive, emotional, evaluative, and behavioral dimensions of identification measured in various combinations, Roccas et al. (2008) distinguish between four conceptually distinct modes of social identification: importance (how much I view the group as part of who I am), commitment (how much I want to benefit the group), superiority (how much I view my group as superior to other groups), and deference (how much I honor and

submit to the group's norms, symbols, and leaders), with all of them having different antecedents and consequences. Another reason for the mixed results may be that ethnic identities are sometimes reduced to a fixed and singular ethnic identity. Yet it is especially the development of complex and flexible identities (including both national and one or more ethnic components), positive intergroup attitudes, and positive intergroup interactions that are the essence of the development of adaptive social identities among adolescents.

The Complex Structure of Multiple Identities

The development of and changes in ethnic identity represent parts of an individual's larger identity project. Especially for ethnic minority individuals, multiple categories are readily available. For them, ethnic identity and identity as a member of the dominant society (national identity) can be thought of as two dimensions of group identity that vary independently, resulting in varying degrees in multiple identities and in- and out-group differentiation (Liebkind, 2006). In acculturation research, an immigrant's ethnic and national identities are thought of as two dimensions of group identity that vary independently; that is, each identity can be either secure or undeveloped. An individual who retains a strong ethnic identity while also identifying with the new society is considered to have an integrated (or bicultural) identity. One who has a strong ethnic identity but does not identify with the new culture has a separated identity, while one who gives up an ethnic identity and identifies only with the new culture has an assimilated identity. The individual who identifies with neither has a marginalized identity. Actual identity categories and the strength of identification with them depend on a number of factors, including characteristics of immigrant groups and of the places where they have settled (Liebkind, 2006; Phinney et al., 2001). A person can also identify simultaneously with multiple minority and/or majority groups and thus show various degrees of social identity complexity or adopt different modes of identity representation at different times, either during different periods of life or under different conditions or emotional states (Roccas and Brewer, 2002).

The multiply identified individuals face two challenges: how to balance the importance of different group memberships, and how to integrate them (Phinney and Alipuria, 1996). Although having multiple important identities may increase the likelihood of conflict between them, multiple ethnic and national identities may also coexist successfully (e.g., Phinney et al., 2001; Verkuyten, 2005). However, interference between multiple central identities are likely if the cultures associated with them differ; Martinovic and Verkuyten (2012) found that the negative relationship between religious and national identification was strong among Turkish Muslims in Germany and the Netherlands who perceived incompatibility between Western and Islamic values and ways of life.

When different social identities do not converge, there are different ways in which the individual may structure the representations of the in-groups to reconcile the competing identities (Roccas and Brewer, 2002). Even when considering only one ethnic identity at the time together with the national identity, the content of the resulting combined identity may include varying proportions of those two components, and these components may be either parallel or hierarchical; immigrants may perceive their own ethnic group and the national out-group as subgroups of a common national in-group (e.g., Verkuyten, 2005). Multiple identification is, however, possible only if the superordinate identity is sufficiently inclusive and facilitates successful intergroup interaction. Also, multiply identified individuals can claim membership in two or more groups only to the extent that they are accepted by others as members of those groups. One major problem is that members of majority and minority groups may have different preferences for the content of the superordinate identity, that is, what that identity and the relations between the subgroups within it should look like. Although both majorities and minorities may prefer identity integration as a goal, majority members may mean a more assimilative identity and minority members may mean a more separate identity with the term (e.g., Verkuyten, 2005).

Ethnic Identity, Well-Being, and the Consequences of Perceived Discrimination

According to a meta-analysis among ethnic minorities in North America (Smith and Silva, 2011), ethnic identification is more strongly related to positive than to compromised well-being. In addition, bicultural identities are both typical and beneficial for psychological well-being (e.g., Berry et al., 2006). Moreover, secure and positive bicultural identity is found to be associated not only with better well-being but also with more positive attitudes toward out-groups (Phinney and Alipuria, 1996).

However, the relationship between ethnic identity and adaptation and well-being is likely to be moderated by a number of additional factors related to social context, such as national policies, local circumstances within the community, and personal relationships. A consistent and robust finding among adults and adolescents alike is that perceived discrimination has direct and strong impact on the psychological well-being and health of immigrants. Perceived discrimination also affects the ways minority group members identify with both minority and majority groups.

However, individuals react differently to the same circumstances; while some may downplay or reject their own ethnic identity, others may assert their pride in their cultural group as a way of dealing with negative attitudes. The different identity reactions available for ethnic minority members to cope with the experience of being discriminated against include (1) seeking to assimilate into the majority by increasing national identification, (2) developing a so-called reactive ethnicity, or (3) reducing national identification. The Rejection-Identification Model (Branscombe et al., 1999) argues, and research has attested, that increasing group identification in response to perceived discrimination can reduce the detrimental effects of perceived discrimination on psychological well-being as the disadvantaged group provides a sense of acceptance and belonging. In some studies, however,

the relationship between perceived discrimination, ethnic identity, and well-being has not been obtained (e.g., Jasinskaja-Lahti et al., 2009). Different factors, such as the lack of cohesion in the immigrant community or initially high identification may prevent immigrants from increasing their identification with the minority group. Instead, ethnic minority individuals may react to perceived discrimination by withdrawing themselves from the superordinate national group, followed by negative out-group attitudes. Thus, as suggested by the Rejection-Dis-Identification Model (Jasinskaja-Lahti et al., 2009), perceived discrimination may in some contexts prevent minority members from developing a sense of belonging to a national superordinate group. However, causal chains are reciprocal; the level of national identification influences changes in ethnic identity as a reaction to perceived discrimination. Fuller-Rowell et al. (2013) found in their longitudinal study that perceived discrimination in the first year of college decreased ethnic identity commitment across the college years among participants with a weaker national identity, but increased ethnic identity commitment among participants with a stronger national identity. Higher levels of national identity were also associated with greater increases in ethnic identity commitment over time.

However, no single model can fully and universally account for the complex interplay between ethnic identity, perceived discrimination, and well-being. In some studies, high in-group identifiers have been found to be harmed more by perceived discrimination, in others high in-group identification has reduced the psychological costs of discrimination and often it has no effect at all (Pascoe and Richman, 2009).

Negotiating Ethnic Identity

Examining ethnic identities on the level of interactions means studying the actual social processes in which people define and negotiate their complex identities in a specific context. When ethnic identities are studied within discursive psychology, the focus is on what people do with their talk and how they do it, for example, in how people make sense of their identities and how groups are discursively formed through talk (e.g., Verkuyten and de Wolf, 2002). Within this approach, ethnic identity is thus conceptualized as a discursive construct and analyzed contextually in terms of discursive action. One can, for instance, examine how social categories are constructed and used in social interaction and with what consequences. For example, classifications used to categorize various immigrant groups can have implications for how they are treated (Goodman and Speer, 2007).

Discursive studies on ethnicity have focused not only on majority group members' constructions of group distinctions and identities, but also on ethnic minority identities. Verkuyten and de Wolf (2002) showed how Chinese people living in the Netherlands used a variety of discursive and cultural resources when constructing and accounting for their ethnic identities in three different ways: The first way called 'being' was ontological in that a biological model was often used in this discourse, where ethnicity was determined by ancestry. In the second discourse, characterized by emotional motivations and called 'feeling', ethnicity was based on the person's own feelings of belonging to the ethnic group. This feeling, in turn, was explained as a result of early socialization. The third discourse was all about 'doing,' that is, the focus was on ways of acting that are typical for this particular ethnic group, for example, language and specific behaviors. Other examples of discursive research on ethnic minorities include Malhi et al. (2009) who found that South Asian-Canadian women preferred hybrid, multicultural identities over monocultural identities when describing themselves, and Ali and Sonn (2010) who explored how Cypriot Turkish people in Australia constructed multihyphenated identities by using different discourses, that is, those of modern Muslims, of language, of phenotype and ancestry, and of generation. Ali and Sonn (2010) concluded that these discourses highlighted both the current sociopolitical context and collective history and constructing hyphenated identities functioned as an act of self-determination and a way of resisting assimilation.

Constructions of ethnic identities are always situated by nature, relevant to a particular time and place. Varjonen et al. (2013) examined the way a group of ethnic Finnish migrants constructed their ethnic identities before and after migrating from Russia to Finland and found that the main interpretative repertoires used when constructing identities both in Russia and in Finland were the biological repertoire, the repertoire of socialization and the repertoire of intergroup relations. Although the process of ethnic migration is officially based on criteria of ethnic Finnish ancestry, Finland turned out to be the very place where the participants stated that being Finnish was impossible. Before migration, participants mostly presented themselves as Finns, whereas after migration Finnish identity was explicitly problematized and a larger variety of self-labels was used.

In Conclusion

Whether one adopts a cognitive or discursive approach, successful integration of multiple identities can be seen as providing means for the individual to construct for himself or herself both insider and outsider positions in relation to more than one ethnic group. Ethnicity can be an important part of anyone's identity, although research on ethnic identity has focused mainly on minority members. This is due to increasing international migration, which has prompted a need for identity negotiations concerning cultural maintenance vs assimilation and minority members' possibilities to combine ethnic and national identities. Clearly, minority groups have less power than majorities to influence the outcome of such negotiations. However, the way a superordinate national identity is defined within a society affects the sense of belonging of minority and majority members alike.

As noted above, ethnic identities are relational, situational, and constantly negotiated in flexible ways. Furthermore, constructing ethnic identity in social interaction does not exclude a relatively stable sense of oneself as a member of one or more ethnic groups, developed over the life span. National majority groups sometimes use essentialist – and therefore exclusionist – criteria for defining the content and boundaries of national identity, depicting ethnic identity as a rather unchangeable

phenomenon. However, also ethnic minority groups sometimes use essentialist arguments about their own 'authentic' identity in order to resist assimilation and to express a wish to preserve their heritage identity. Thus, essentialist arguments – or any other arguments members of minority and majority groups may use in defining their ethnic identities – are neither 'good' nor 'bad' as such. Which arguments people will use in defining themselves in interaction depends on where and with whom they are, and who they want to be in that particular situation. The authors therefore emphasize the deeply social nature of ethnic identity. In addition, as multiple identities are both increasingly typical and often beneficial for psychological well-being, there is no reason to reduce ethnic identity to a fixed and singular entity but to encourage the development of complex and flexible identities that include both national and one or more ethnic components.

Ethnic Intermarriage

Abstract

Ethnic intermarriage is often used as measure of social distance between ethnic groups. This article presents statistics on the prevalence of intermarriage and reviews theories of marriage which might be helpful when interpreting these statistics. After a review of the empirical literature on the determinants of interethnic marriage, the article ends with a discussion of its consequences both for those directly involved and for society as a whole.

Ethnic intermarriage occurs when people from two different ethnic groups marry each other. While ethnicity is always used to describe people with similar cultural attributes (such as language, cuisine, and dress), because it is socially defined, the notion of ethnicity can differ across societies. This article will focus on the determinants and consequences of ethnic intermarriage in the US, but the issues discussed are applicable in many contexts.

Significance of Ethnic Intermarriage

Intermarriage rates are often used to measure social distances between groups. These marriages typically only occur in large numbers after a minority group has adopted the cultural patterns of the mainstream. Not only are they reflective of assimilation and ethnic acceptance among those in the marriage, but also they generate interethnic commingling among family members, friends, and broader social networks which in turn results in further assimilation and acceptance. In contrast, marriage within ethnicity, or ethnic endogamy, simplifies the transmission of ethnic traits to new generations and in this way perpetuates the distinctions between ethnic groups.

Given the view of interethnic marriage as the final stage of assimilation (Gordon, 1964), analyses of marriage patterns can offer insights into whether today's immigrants are integrating as rapidly as those in the past, whether some groups assimilate faster than others, and to which segments of the host society immigrants and their descendants assimilate.

Prevalence of Intermarriage

According to a recent Pew Research Center report (Wang, 2012), 6.8% of all new marriages in the US in 1980 involved people of different races or ethnicities while the corresponding figure in 2010 was 15. The report defines out-marriage as a marriage between people from different racial groups or a marriage between a Hispanic and non-Hispanic regardless of race. Among the 2010 newlyweds, whites had the lowest rate of out-marriage (9%) followed by blacks (17%), Hispanics (26%), and Asians (28%). There were no meaningful gender differences in intermarriage tendencies for whites and Hispanics, but black males were significantly more likely to marry outside of their race than black females and Asian females were more likely to out-marry than Asian males (Wang, 2012).

While statistics based on this very broad race–ethnicity-based conception of intermarriage are certainly informative, they can mask interesting patterns that surface when using country of origin or ancestry to measure ethnicity. **Table 1** shows endogamy rates by nativity and year for the 20 most populous ancestries in the US in 1980. Statistics are computed using the 1980 Census and 2008–10 American Community Surveys. A marriage is considered endogamous if the first self-reported ancestries of the spouses match. As can be seen in the table, the foreign born have significantly higher endogamy rates than the native born. This pattern is consistent with the notion that immigrants are less assimilated and so are likely to have less in common with potential spouses of different ancestries. However, since many of the foreign born may have

Table 1 Endogamy rates by ancestry, year, and nativity

	1980		*2008–10*	
	Native born	*Foreign born*	*Native born*	*Foreign born*
Danish	7.8	30.1	5.6	24.0
Dutch	18.3	46.6	15.4	26.4

Japanese	74.2	50.1	42.3	45.4

Notes: Endogamy rates computed using data from the Integrated Public Use Microdata 5% state sample of the 1980 Census along with the 2008–10 American Community Surveys.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.31097-2

arrived in the US already married, this result might also be explained by their not having the opportunity to marry outside of their ethnicity. The table also shows that, except for the foreign born in three ethnic groups, endogamy rates were lower in 2008–10 than they were in 1980, a trend consistent with recent findings of increasing acceptance of intermarriage (Wang, 2012). Perhaps most noteworthy in the table is the considerable degree of heterogeneity in endogamy rates across ancestries. In order to properly interpret these relationships, it is useful to consider what drives marriage decisions.

Theories of Marriage

Social exchange theory was the first framework developed for understanding intermarriage decisions (Davis, 1941; Merton, 1941). It implies that if whites face higher social costs of interracial, black–white marriage, as compared to blacks, then the white spouse must be compensated for such marriages to actually occur. This compensation might often come in the form of higher socioeconomic status of the black spouse.

Empirical analyses of social exchange yield mixed results. Because taboos against interracial marriage have diminished greatly through the years (Wang, 2012), some of the discrepancies across studies are due to differences in when the study was conducted. However, even when using the same data source, researchers arrive at divergent conclusions because of differences in empirical approach (Gullickson and Fu, 2010; Kalmijn, 2010; Rosenfeld, 2005, 2010). Regardless of methodology, the degree of empirical support for social exchange theory differs across racial groups (Fryer, 2007; Qian, 1999).

The theory of marriage developed by Gary Becker (1973) predicts exchange on some characteristics but matching on others. He conceptualized households as small firms producing 'commodities' such as children, health, companionship, food, and clean clothes. Since these commodities typically require money and time to produce, the model implies exchanges between high-wage men who specialize in the labor market and low-wage women who specialize in domestic skills. The theory also implies matching on characteristics when these matches would make the couple more efficient at producing commodities. For example, spouses with the same ethnic background can more efficiently 'produce' children with ethnic traits.

David Lam's theory of marriage (1988) focuses on couples' joint consumption, as opposed to production, of household goods. The theory predicts that optimal matches are made based on similar demands for household public goods. Because many of the goods shared among family members are ethnicity-based (ethnic traits in children as well as ethnic meals and vacations to the home land), then it is optimal for individuals with similar demands for these goods to marry. Given the emergence of labor-saving household technologies such as microwaves and dishwashers as well as a functioning service industry that enables families to outsource many household activities, today's couples seem to form family based more on consumption complementarities of the type proposed by Lam than on production complementarities proposed by Becker (Stevenson and Wolfers, 2007). Nevertheless, all three marriage models either directly imply or are consistent with high rates of ethnic endogamy and can provide insights into the types of people that are most likely to intermarry.

Determinants of Ethnic Intermarriage

As there is no clear way to measure ethnicity in a US context, empirical studies of ethnic endogamy use several different measures. Most research is limited to the variables available in the large population-representative surveys (Census and Current Population Survey (CPS)): race, Hispanic ethnicity, ancestry, country of birth, and parents' countries of birth. More detailed country of origin information for people that have been in the US for several generations is also available for some Asians and Hispanics. While the variety of ways ethnicity can be defined can make detailed comparisons between studies difficult, the distinctions are not generally very important given the correlations between categories. For example, immigrants born in Japan or second-generation immigrants with Japanese parents typically list a Japanese ancestry. That said, to err in the side of caution, the discussion below focuses on the drivers of intermarriage that tend to be robust across studies.

The determinants of ethnic intermarriage can be separated into three main categories: ethnic preferences, preferences for characteristics which are correlated with ethnicity, and marriage market characteristics.

Ethnic Preferences

Both the Becker and Lam theories of marriage predict that people who are more connected to their ethnic backgrounds are more likely to marry within their ethnicities. By exchange theory, those who are less integrated may need to be more highly compensated before agreeing to out-marry. It should not be surprising, therefore, that immigrants who arrive in the US at an older age or have been in the country for less time are more likely to choose a same-ethnicity spouse (Qian et al., 2012; Chiswick and Houseworth, 2011). Similarly, immigrants who are less fluent in English are more likely to marry endogamously (Bleakley and Chin, 2010).

Ethnic preferences also play a role for second- and later generation immigrants. While the native born are typically fluent in English, their marriage decisions often depend on whether English is their mother tongue (Stevens and Swicegood, 1987). Regardless of language ability, US-born children of immigrants can be sensitive to their parents' preferences for their spouses. This is consistent with the evidence that ethnic endogamy is more prevalent among those marrying young (Chiswick and Houseworth, 2011) and those from countries with traditions of marrying young (Kalmijn and van Tubergen, 2010) but less prevalent among those marrying for the second and third times (Chiswick and Houseworth, 2011).

In addition to early life experiences, acceptance of different cultures might result from events and experiences occurring later on in life. Participation in the Armed Forces may broaden people's worldview as a result of being stationed overseas or sharing barracks with Americans of different ethnicities within

the US (Fryer, 2007). Military experience is indeed positively correlated with out-marriage (Furtado and Theodoropoulos, 2011; Chiswick and Houseworth, 2011).

Education may also give rise to a more worldly view which might make people more comfortable sharing a home with someone with different cultural attributes. While the highly educated tend to be less prejudiced toward ethnic and racial minorities (Hello et al., 2002), researchers have found conflicting evidence on the relationship between education and the strength of ethnic identity (Duncan and Trejo, 2011; Feliciano, 2009). After accounting for other mechanisms through which schooling affects marriage, researchers using data from recent years provide evidence that education decreases preferences for ethnic endogamy (Furtado and Theodoropoulos, 2011; Kalmijn, 2012), but Furtado (2012) does not find any evidence of this relationship using 1970 data.

Preferences for Related Characteristics

High rates of ethnic endogamy may not be driven by ethnic preferences per se, but by preferences for other characteristics that are correlated with ethnicity. For example, given the large role played by family in the rituals and practices of many religions, it may not be surprising that religious homogamy rates are quite high (Sherkat, 2004). Preferences for a spouse with the same religion can ultimately result in high rates of ethnic endogamy given the strong relationship between ethnicity and religion. It may be challenging, for example, for a Hindu spouse-searcher to find a non-Indian Hindu.

It is difficult to analyze the role of religion in interethnic marriage decisions because of the lack of information on religion in most nationally representative surveys in the US. However, the percentage of the country of origin that is, Christian has been found to decrease endogamy among childhood arriving immigrants and the native-born children of immigrants in the US (Kalmijn and van Tubergen, 2010). Using data from Sweden, Dribe and Lundh (2011) provide evidence that several cultural factors, including religion, play a role in explaining endogamy rates.

While religious homogamy is generally decreasing (Sherkat, 2004), assortative matching on education has increased since the 1960s (see Schwartz and Mare, 2005, for a discussion of potential explanations). Given the importance of matching on education and the variation in average schooling levels across ethnic groups, individuals with education levels that are typical within their ethnic group may end up marrying endogamously simply because it is relatively easy to meet a coethnic with a similar level education. On the other hand, ethnics with education levels that deviate from the norm within their ethnicity are likely to find it more difficult to find a same-ethnicity and same-education spouse and so compromises must be made.

Several studies have found that the closer a person's own education is to his ethnic group's average, the more likely he is to marry endogamously (Chiswick and Houseworth, 2011; Kalmijn and van Tubergen, 2010). Furtado (2012) and Furtado and Theodoropoulos (2011) show that an increase in schooling leads to a decrease in the probability of marriage within ethnicity for people in low-education groups but an increase for those in education ethnicities. Consistent with this evidence, Kalmijn (2012) shows that education increases out-marriage most in low-education groups and least in high-education groups. Interestingly, he never finds that education increases endogamy, not even in the most highly educated groups. He hypothesizes that, as discussed above, education tends to decrease in-group preferences so that while the highly educated members of high-education groups have access to same-education, same-ethnicity spouses, they may not value ethnic endogamy to the same degree as those with less education.

Schooling may also affect marriage patterns via the preferences of marriage-market participants who do not identify with any particular ethnic background. For example, it may be that, as predicted by exchange theory, people are only willing to marry ethnic minorities, especially those with strong ethnic attachments, if they are compensated in the form of a spouse's higher education (Gullickson and Fu, 2010). It may also be that ultimate marriage patterns are driven by the majority population's perceptions of ethnic minorities, perceptions that are likely to be influenced by average schooling levels of the ethnic group. Kalmijn (2012) finds that, conditional on a person's own education, belonging to a group with a higher average education is associated with an increase in the likelihood of out-marriage. He interprets this result as evidence of the importance of natives' perceptions of a person's ethnic group.

Marriage Market Characteristics

Besides preferences, intermarriage patterns are driven by opportunities to meet people from different ethnic groups. It is certainly easier for a person belonging to a large ethnic group to find an attractive match within ethnicity. Indeed, whites, the majority race in the US, have higher racial endogamy rates than any other group despite the fact that when racial minorities out-marry they typically marry whites (Wang, 2012). Opportunities to meet same-ethnicity mates are also driven by residential segregation patterns. The decline in Hispanic intermarriage in the 1990s can be explained partially by increases in Hispanic residential segregation (Lichter et al., 2007).

In order to take into account both the size of the ethnic group and residential segregation, studies typically look at the impact of the proportion of a person's neighborhood or city that is of the same ethnicity. Studies consistently find a strong association between this variable and the probability of in-marriage (Chiswick and Houseworth, 2011; Kalmijn and van Tubergen, 2010), but caution is required when interpreting this result since people with stronger preferences for endogamy are likely to choose to live around coethnics. In addition, residential segregation can reinforce group solidarity and ethnic identity (Lichter et al., 2007). Regardless of what exactly drives the relationship between ethnic group size and endogamy, it is important to keep in mind the distinction between opportunity and preferences when interpreting changing endogamy rates over time or comparing endogamy rates across ethnic groups.

Another marriage market characteristic that drives intermarriage patterns is sex ratios. Males in groups with larger male to female ratios in the US are likely to find it more difficult to

meet suitable same-ethnicity spouses whereas the opposite would be true for females in these groups. Sex ratios have been found to predict interethnic marriage for both first- and second-generation immigrants (Angrist, 2002; Chiswick and Houseworth, 2011), but this relationship is not as robust as that of between ethnic group size and endogamy as some studies find no effect (Kalmijn and van Tubergen, 2010).

Variation in the availability of same-ethnicity potential spouses may also arise from changes in the flow of new immigrants to the US. A steady immigrant inflow from Mexico in the past century provides many potential same-ethnicity partners for Mexicans of all generations (Lichter et al., 2007). New immigrants also help sustain institutions, such as churches and newspapers, which facilitate social interactions within ethnicity. Stevens and Swicegood (1987) find that belonging to an ethnic group with many non-English speakers, either because of a large number of immigrants in the group or because second- and later generations continue to speak their origin language, increases endogamy rates even among people whose first language is English. They attribute this result to the role of language in shaping socialization experiences and ethnic identification regardless of one's own preferred language.

Consequences of Intermarriage

Interethnic marriage patterns are often used as measures of assimilation not only because more assimilated groups are more likely to intermarry but also because intermarriage results in further integration. While it is true that those with better English-speaking skills are more likely to marry outside of ethnicity, sharing a household with a native English speaker is likely to further improve a person's English proficiency. In a similar way, immigrants married to natives are likely to learn more about US customs and traditions.

Intermarriage affects those directly involved in the marriage as well as the communities surrounding these marriages. Children of intermarried couples are less likely to identify with an ancestry (Duncan and Trejo, 2011). Moreover, an intercultural marriage typically brings together two sets of families, friends, and acquaintances that most likely have different cultural attributes. This ethnic commingling breaks down barriers between ethnic groups.

Several studies have found a positive relationship between marriage to a native and wages of immigrants in several different countries (Meng and Gregory, 2005, for Australia; Meng and Meurs, 2009, for France; Kantarevic, 2004, for the US, Çelikaksoy, 2007, for Denmark). Since the natives that immigrants marry are most often from different ethnicities (Furtado and Theodoropoulos, 2010), we can think about these marriages as interethnic. Furtado and Theodoropoulos (2010) find that immigrants arriving in the US before age 19 are more likely to be employed if they are married to a native than if they are married to another immigrant.

The problem with interpreting these relationships is that it is unclear whether marriage decisions directly affect worker productivity and job matching or, as discussed in the previous section, whether productive immigrants with better networks are more likely to marry natives. Studies that have taken steps to correct for this by focusing on people compelled to out-marry as a result of marriage market conditions instead of personal preferences have generally continued to find positive effects of marrying a native (Meng and Gregory, 2005; Furtado and Theodoropoulos, 2010). Furtado and Theodoropoulos (2010) examine the mechanisms through which marriage to a native increases employment rates of immigrants. They find little to no evidence that the returns to marrying a native are driven by undocumented immigrants' gaining the right to work legally in the US but provide several pieces of evidence suggesting that connections to native social networks play an important role for all childhood immigrants.

Intermarriage patterns also have important implications for the interpretation of the most commonly used measures of intergenerational assimilation in the US. While the CPS asks questions about parents' countries of birth, 1970 was the last time the Census asked for this information. No national survey asks for grandparents' countries of birth. Thus, when attempting to measure intergenerational assimilation beyond the second generation, researchers typically rely on self-reports of ancestry or ethnic background. This may result in biased estimates of intergenerational mobility, especially among descendants of mixed marriages, if the likelihood of identifying with a particular ancestry is associated with a person's education and labor market success. Duncan and Trejo (2011) present evidence that high-skilled Mexicans are less likely, relative to low-skilled Mexicans, to marry other Mexicans and that children of these mixed marriages are less likely to identify as Mexican. These two facts, in conjunction with intergenerational transmission of skill, imply that Mexicans in third and higher generations will be more likely to self-report Mexican ancestry if they are low skilled. This is exactly what they find in the data suggesting that the commonly constructed estimates of intergenerational assimilation for Mexicans are too low.

Conclusion

As argued throughout this article, interethnic marriage rates can be interpreted as a measure of social distance between groups. Not only is intermarriage more likely when groups are more integrated into mainstream society, but marriage further integrates ethnic groups. In fact, intermarriage has been referred to as the spoon that stirs the ethnic melting pot (Lichter et al., 2007).

Recent statistics suggest that intermarriage rates, although increasing, are still quite low. Perhaps even more interesting is the variation across ethnic groups in the likelihood of intermarriage. While it may be tempting to interpret changes over time and differences across groups solely in terms of preferences, the literature suggests that many structural factors drive endogamy rates. Regardless of the causes of intermarriage, a union of two people with different ethnic backgrounds begets many social interactions between the couple's social circles resulting in further breakdowns of ethnic barriers. Children of interethnic marriages tend to have weaker ethnic identities and are themselves more likely to marry outside of ethnicity. Thus, further analysis of the causes and consequences of ethnic intermarriage is certainly warranted given its role as

a barometer of current levels of assimilation and ethnic relations as well as a forecaster of future levels of immigrant integration.

Ethnic, Racial, and Nationalist Movements

Susan Olzak, Stanford University, Stanford, CA, USA

Abstract

Ethnic, racial, and nationalist social movements organize around distinct ethnic identities, but they differ with respect to the scope of their claims, activities, and goals. Ethnic nationalist movements can be distinguished empirically from ethnic/racial movements by the presence of demands claiming legitimate rights to sovereignty and/or authority to administer a specific territory. As a result, nationalist movements are likely to come into conflict with existing state authorities and the international system. Theories explaining the rise, persistence, and decline of these movements vary with respect their emphasis on cognitive, rational, or instrumentalist motivations for such movements, and to the degree these movements come in conflict with state authorities.

Introduction and Definitions

Though they are commonly analyzed separately, ethnic, racial, and nationalist (E/R/N) movements voice strikingly similar claims of sovereignty rights and ethnic integrity. Race is conventionally defined in terms of putative biological or inherited features, while ethnicity tends to refer to cultural and acquired traits such as language, religion, and custom. Various combinations of claims, goals, tactics, and organizational forms distinguish different types of E/R/N movements. This section first establishes some working definitions for ethnic and nationalist social movements, lists various forms of E/R/N movements, and then briefly reviews several relevant research traditions.

Social movements generate collective action advocating fundamental changes in the political or economic arrangements in a society. Social movements typically involve sustained activity over time and place (whereas collective action may be fleeting). Most scholars also find that adherents of a social movement tend to support a coherent ideology that defines its core identity.

The defining features of ethnic and racial social movements (E/R) are that claims are made based upon particular identity or boundary, defined by the presence of racial or ethnic markers (Barth, 1969). These markers typically include skin pigmentation, ancestry, language, and a history of discrimination, conquest, or other shared experience. Recent research tends to subsume racial and ethnic movements under the label of ethnicity. This is due to the fact that distinct biological characteristics do not easily allow observers to distinguish among categories that are fluid, fuzzy, and permeable. For simplicity (and to avoid invoking unscientific assumptions about the genetic basis of race), most researchers prefer the more generic label of ethnicity (Brubaker, 2004).

Successful challenges from E/R/N movements depend upon levels of group solidarity and mobilization capacity. In order to examine the effect of these factors on movement outcomes, it is necessary to distinguish a movement's mobilization capacity apart from ethnic solidarity. Solidarity is characterized as the conscious identification (and loyalty) with a particular race or ethnic population, measured by attitudes, institutional involvement (or organizational participation), and monitoring capacity. Mobilization is the capacity to harness resources (including solidarity, organizations, and material resources) in an effort to reach some collective goal. The US civil rights movement is a prototypical E/R social movement. As a template for collective action, the civil rights movement generated many subsequent movements (and countermovements), including the antiapartheid movement in South Africa, rights movements for Muslims in Western Europe, and many other settings (Andrews, 2013).

While race and ethnic movements make reference to a shared identity based upon cultural markers, phenotype, outward expressions of loyalty, celebrations, violation of minority rights, or in- and out-group labels, nationalism is a social movement making a territorial claim. According to Hechter (2000), nationalist movements articulate claims for self-determination and authority over a specified territory and espouse grievances based upon the fact that these demands are not now being satisfied. Ethnic nationalism also includes references to shared ethnic identity as a basis for these demands.

The pursuit of sovereignty rights typically also provokes conflict (and perhaps also warfare) with existing regimes. Such conflict can remain quiescent for long periods of time, erupting suddenly into full-blown armed guerrilla warfare, or civil war, depending on regime strength, outside support, primary export commodities, internal mobilization of resources, and reaction by state authorities to nationalist movements (Fearon and Laitin, 2003, 2005).

However, nationalist movements do not always organize around race or ethnic identity. Instead, they may rest upon a group's geographical concentration, political jurisdiction and leadership, and/or legacy claims to legitimate authority. Some scholars refer to this as 'civic nationalism,' in which national identity crosscuts ethnic identities. Civic nationalism is often characterized as more inclusive, as in multiculturalism (but see Brubaker, 2004).

Brubaker (1996: pp. 6–12) categorizes nationalism as one of the three types of collective action mobilized by national minorities, nationalizing states, and external national homelands. This tripartite definition has the advantage of analyzing nationalism as a confrontation with an existing

regime, empire, colonial power, or host nation. Put differently, ethnicity becomes transformed into nationalism when it makes specific historical claims and attempts to administer the group as a political community.

Social movement perspectives add the insight that E/R/N movements can be further distinguished by their relative duration, target, tactics, violence, and audience. These distinctions yield eight broad categories: (1) autonomy movements that demand special rights over a particular territory; (2) civil rights protests that demand expansion of a group's civil and economic rights or demand an end to discrimination; (3) antagonist movements directed against specific ethnic targets, including collective attacks ranging from genocide, ethnic cleansing, and mob violence, to symbolic threats; (4) state-strengthening nationalism, which attempts to unify diverse cultures (state-building nationalism) or merge politically divided territories into one state (unification nationalism); (5) secession movements claiming rights of withdrawal from formal state authority (to join or form a newly independent state); (6) separatist movements demand their own state authority which involves replacing existing state authority and administrative powers; (7) irredentist movements are those that claim rights over a territory currently administered by another state authority; and (8) genocide or ethnic cleansing, which is an extreme form of violent social movements against a target population which aims to either annihilate or remove an entire population.

While these definitions clarify some important distinctions, the application of these terms often becomes tricky when conducting research on E/R/N movements because race and ethnic boundaries are porous, dynamic, and flexible. From different political vantage points and at different times, the same movement may be seen as engaging in senseless violence or as a nationalist liberation movement. Moreover, movements adopt new goals and tactics to adjust to shifts in the political environment. Such changes by movements may engender fears that a movement's original authenticity has become compromised or coopted. While these transformative qualities of social movements undoubtedly create difficulties for researchers, there is a hidden advantage as well. Taking these shifts into account might reveal new information about how group identity becomes transformed into social movements.

Core Research Questions

Questions about the origins, persistence, and success of movements drive the majority of all social science research efforts in this area. First, how does ethnic, racial, religious, territorial, or national identity become transformed into active social movements? This question underscores the importance of maintaining a distinction between cultural or symbolic expressions of identity (e.g., ethnic self-help organizations, immigrant festivals, head scarves) from social movements that express claims for expanded rights to some set of authorities, or violence directed against specific groups. Accordingly, scholars ask under what conditions will specific boundaries (e.g., language vs. skin pigmentation) come to be politically activated. In other words, it is important to frame the salience of ethnicity in social movements as something to be explained.

Second, are the factors explaining the emergence the same as those that encourage the persistence of E/R/N movements? Until recently, social scientists have focused mainly on the internal characteristics of states to explain E/R/N movements. Thus poverty, rough terrain, imposition of direct rule, warlord corruption, or some other structural feature of the political system or economy triggers have been identified as factors raising levels of insurgency (Fearon and Laitin, 2003). Others have drawn attention to the advantages of viewing social movements as a function of global and transnational mechanisms that encourage ethnic insurgency (Olzak, 2006, 2011). Still others emphasize the importance of the existence of ethnic grievances driven by ethnic exclusionary practices directed against less powerful minorities (Esteban et al., 2012; Wimmer, 2002).

A third question asks, are ethnic movements truly novel, or are they simply political movements that once, earlier in history, adopted other forms? Without undertaking a long historical perspective, answering this question is difficult. However, it seems plausible that social movements are now more likely to be couched in distinctly ethnic terms, as a function of self-determination norms and UN declarations on minority rights. Instead, for most scholars, evidence that these movements are modern rests on emergence of a shared identity of a 'people' with boundaries beyond a parochial village or kinship group (Anderson, 1991; Brubaker et al., 2006). The irony is that many 'modern' nationalist movements (e.g., Islamic nationalist movements) have invoked themes demanding return to the past.

A fourth orienting question concerns the shift in the scope of activity: What are the mechanisms that cause E/R/N movements to expand their scope from local concerns to encompass national goals? Brubaker (1996) describes 'nationness' as an institutional process that begins to crystallize with state-expansion. Hechter's (2000) theory asserts that nationalist movements reacted to the implementation of direct rule by an external colonial or imperialist power. Global perspectives suggest that the density of international connections among states may be reducing the significance of social movements bounded by national borders (Olzak, 2006).

Another set of issues raise questions about the nature of the relationship between the existence of ethnic divisions and the likelihood of internal civil war. For instance, they ask, under what conditions does the activation of ethnic boundaries promote armed conflict or separatist insurgencies? Several lines of research have suggested that there is a strong link between ethnic cleavages and violence, in which group differences mobilize and sustain the capacity for groups to incite civil wars. For instance, Sambanis (2001) finds that civil wars based upon ethnic and/or religious identities are more likely to erupt in countries with high levels of ethnic heterogeneity and low levels of political democracy (but see Fearon and Laitin, 2003).

Scholars have also explored the reverse causal argument. In this view, economic (or political) instability results from prior conflict, or that economic decline follows the public's anticipation of civil unrest. In an attempt to sort out the causal ordering of economic effects on ethnic wars, current empirical evidence supports the notion that economic decline raises rates

of internal civil war, rather than the reverse, but that political instability and state strength may be endogenous to the process of ethnic and nationalist mobilization (see Olzak, 2004).

While the evidence connecting ethnic diversity to the onset of armed conflict has been equivocal, ethnic diversity may prolong the duration of civil wars. Fearon and Laitin (2003) find that the duration of violent civil conflict increases when there are a small number of large ethnic groups, when there are conflicts over land use, and when rebels have access to external (or contraband) resources.

Leading Theoretical Perspectives

Perspectives offering explanations of the emergence, growth, and decay of E/R/N social movements emphasize one or more processes of changing economic, political, or social conditions. Each tradition has generated a number of important empirical studies, which are linked together by common theoretical concepts and mechanisms.

Colonialism and Ethnicity

The legacy of colonialism provides a number of instructive lessons for understanding the emergence and timing of nationalist movements. Territorial boundaries drawn during periods of colonialist rule (especially in Africa and the Middle East) provide examples of how colonialism encouraged ethnic cleavages that subsequently form the basis of independence movements based upon ethnic nationalism. During periods of state-formation, outcomes depend upon complicated negotiations between opponents, nation-builders, and external participants. As norms of self-determination gained momentum internationally, colonialist regimes became perceived as wielding illegitimate power over the indigenous population. As a result, nationalist movements of independence often adopted an ethnic character, often in contradistinction to colonialist racial/ethnic identities.

E/R/N movements are fundamentally embedded in (often contradictory) legends and myths about various group identities and actions that have shaped their histories. Language, religion, immigration, and migration histories all play a role in building the defining characteristics of a region. However, periods of nation-building that coincide with independence movements apparently play a central role in determining the nature of identity of an imagined 'nation.'

State- and Nation-Building Processes

Theorists once assumed that the processes of state-building (obtaining legitimate authority and administrative rights to govern a territory) and nation-building (building a sense of shared identity in a population) should be analyzed as an evolutionary set of stages, such assumptions seem naive today. Evidently the process of creating a legitimate nation with an accepted system of authority and leaders is better conceptualized as a dynamic set of negotiated meanings (Brubaker, 1996). National identities and ethnic communities are constantly being reconstructed and boundary lines redrawn.

Anderson (1991) provided a useful starting place for understanding why nationalist and ethnic movements aim to reconcile the lack of correspondence between state boundaries and national identity. Hechter (2000), Fearon and Laitin (2003), and many others have emphasized the fact that few (if any) nation-states are homogeneous entities; not only do states sometimes encompass many nations (as in the notion of multiculturalism) but national movements can exist without espousing goals of statehood. If a 'nation' is demarcated by a self-identified boundary, then one nation may be dispersed across multiple state boundaries (as in the concept of a Kurdish nation). Such movements may eventually express goals of creating a new state organized around a common national identity. However host states will nearly always resist these movements, often with force. This implies that, even if they are only temporarily successful, ethnic movements can undermine attempts at state-building that assume that state and nationality boundaries are coterminous.

The literature on state-formation has suggested that ethnic movements are most likely to turn violent during early periods of state-formation, when issues of power and authority remain unresolved (Hechter, 2000). E/R/N movements are likely to confront newly independent (or newly democratic) regimes that have not completely won the hearts and minds of all inhabitants. Outcomes depend upon a complicated power balance among opponents, nation-builders, or external states, each of whom may have conflicting interests.

Initial periods of state- and nation-building also play a central role in determining the nature of the identity of an imagined 'nation' (Anderson, 1991). In this view, nations are 'birth marked' by prior conflicts – marked by religion, region, ethnicity, anticolonialism, or conquest – that prevailed during a formative historical period. Violence is especially likely when state-building efforts activate resistance movements based upon these historic cleavages.

Economic and Instrumental Approaches

This tradition rests on the assumption that ethnic movements are better analyzed in terms of politically and/or economically motivated demands rather than instigated by primordial ethnic identities (Blattman and Miguel, 2010). One prominent version of this line of argument suggests that ethnic social movements are based upon shifts in economic inequalities among ethnic groups. Other instrumentalist positions emphasize that ethnic movements are led by social movement leaders who use ethnic identities to gain leverage over competitors in contests for political power.

Competition Theories of Race and Ethnic Relations

Competition theories of race/ethnic movements emerged to explain the puzzle prompted by the empirical failure of modernization theory to account for the apparent rise in E/R/N movements in both developing and developed countries. Competition theories of race and ethnic relations suggest that development encourages competition to the extent that declines in ethnic and racial disadvantage occur. This in turn triggers efforts by dominant groups to exclude competitors, using both legal and illegal methods against minorities

(Olzak, 1992; Olzak and Shanahan, 2003). Lynching, ethnic cleansing, and exclusionary laws are prominent examples of strategies used against minorities (Olzak, 2013).

Competition theory has been supported by empirical studies of Chinese laborers, United States labor movement, contemporary South Africa, analyses of postindustrial racial conflict in the United States, analyses of race and ethnic conflict in cities, and of lynching in rural areas in nineteenth-century United States, and the former republics of the Ukraine, Latvia, Estonia, and Lithuania (Beissinger, 2002; Olzak, 2004).

Rational-Choice and Game-Theoretic Approaches

Rational-choice theorists state that modern ethnic movements occur with regularity because ethnic groups lower monitoring costs and increase benefits attached to ethnic mobilization, allowing ethnic groups to overcome the free-rider problems attached to other types of mobilization efforts (Hechter, 2000). The US civil rights movement has also been analyzed within a rational-choice framework that emphasizes how mobilization that increases disruptions and concession costs to elites has proven decisive to successful movement outcomes (Luders, 2010).

Because ethnic groups are able to form dense social networks easily, costs of monitoring commitment are minimized, which fosters ethnic mobilization. Building on rational-choice models, Fearon and Laitin (1996) have linked the strategic aspects of ethnic identity to violence, as elites build on existing ethnic loyalties (see also Petersen, 2002). Such loyalties can prove fatal to group members. Moreover, the presence of genocidal norms (defined as a threat of sanctions to in-group members who decline participation in ethnic mayhem) increases the scale of ethnic violence. This perspective offers an explanation for one persistent and counterintuitive finding in the literature: Despite a history of intergroup cooperation, tolerance, intermarriage, and trust among different groups interacting within a region, the intensity of ethnic cleansing and violence can remain high, due to the presence of genocidal norms.

Similarly, theorists have extended these ideas to consider the implications of game theory for ethnic mobilization, including outbreak of ethnic war (Fearon and Laitin, 1996). While armed ethnic rebellions tend to last longer than nonethnic ones (Fearon, 2004), a variety of ethnic and cultural characteristics have few systematic effects on the onset or duration of civil wars in general (Fearon and Laitin, 2003).

Political/Institutional Approaches

Political perspectives emphasize the role of shifts in political constraints and opportunity structures that influence the trajectory of E/R social movements. These theories emphasize institutional arrangements, court rulings and reforms, and regional concentration of ethnic populations as viable political instruments leading to mobilization. Two studies from India illustrate these points. For instance, Chandra (2004) argues that political systems based upon ethnic patronage systems can inadvertently provide the foundation for permanent hostilities. Alternatively, Varshney (2002) finds that when business, civic, and voluntary associations integrate and/or crosscut ethnic lines, ethnic confrontations are significantly less likely to erupt (see also Horowitz, 2001).

In cross-national studies of the influence of political structures, some scholars have emphasized the centrifugal force of ethnic political parties, which maintains ethnic loyalties through institutional arrangements and patronage based on ethnic loyalties. Such forces produce fierce loyalties when language, religion, or some other marker also distinguishes a population that is geographically concentrated (Fearon and Laitin, 2003). Other scholars have emphasized proximate causes or triggering mechanisms, such as political changes in authority, collapse of colonial authorities or empires, or transition to market economies, which presumably increases ethnic inequality and promotes ethnic competition (Chua, 2003).

Political structures can be arrayed along a continuum that indicates the extent to which political parties become ethnic vehicles for contesting power. One view of ethnic party systems ('consociationalism') holds that these arrangements reduce ethnic tensions by channeling extrainstitutional mobilization and energy within institutionalized party contests. Alternatively, ethnic parties may instead actively encourage ethnic mobilization because they render ethnic boundaries more salient. Wilkinson (2004) finds empirical support for this argument, reporting that states with a high degree of institutionalization of ethnic parties in states in India produces significantly higher rates of ethnic violence and hostility (see also Varshney, 2002).

Weak States, Regime Instability, and Ethnic Mobilization

States often respond to challenges from nationalist movements by alternating between strategies of repression and concession (Hechter, 2000). For example, the evidence suggests that states shift from strategies of repression to accommodation, depending on both the virulence of dissident protest behavior and state capacity to repress these challenges. However, others have suggested the intriguing hypothesis that it is the vacillation of states itself that incites nationalist violence, signaling a weakness in the state's internal capacity to act (Olzak, 2004).

The potential for ethnic separatism also influences the intensity of collective violence in a country and this effect is stronger in states with weakened political institutions. Evidence from civil wars in Bosnia and Kosovo provide another example of how regime instability shapes opportunities for E/R/N movements. At the same time, policies that involve ethnic resettlement programs often concentrate ethnic populations and create new networks that provide new recruits for mobilizing ethnic violence, as examples from the West Bank in Israel, or the Kurds in Germany, suggest. Thus transitions to democracy may mobilize ethnic movements by offering new political advantages to ethnic groups that were more easily submerged in repressive regimes.

The imposition of external political authority on ethnic minorities compared to imposition of structures of indirect authority has important consequences for ethnic and nationalist movements. Hechter (2000) has argued that the seeds of nationalist movements are embedded in specific political structural arrangements in which a colonial or federated authority cedes formal authority to local leaders. Under such conditions, local elites are delegated political power and authority by centralized authorities, yet the power of local

elites is fundamentally based upon regional identities and loyalties. When central authority is weakened or challenged (by external events such as war, famine, or economic crises), or when central authority is withdrawn (as in the case of the Soviet Union), local elites can mobilize on the basis of regional/ethnic identity.

Institutional Forms of Ethnic Exclusion

Wimmer et al. (2009) emphasize an argument that suggests that the form E/R/N movements will take depends upon a regime's formal institutional arrangements that exclude or privilege members of ethnic populations. Exclusion can take the form of formal disenfranchisement (as in the case of South Africa under apartheid), or more discriminatory patterns of ethnic favoritism, clientelism, and other forms (Wimmer, 2002). Research consistent with this perspective suggests that ethnic conflict peaks under conditions in which exclusionary practices, demographic polarization, and ethnic inequality interact (Esteban et al., 2012; Blattman and Miguel, 2010).

Brubaker (2011) reflects these themes in his work on ethnonationalism in former Soviet states. While some have argued that ethnic tensions and nativist movements have arisen as Soviet power and authority (and resources) related to Cold War alliances declined in importance, Brubaker (2011) argues that the federated system of regional and ethnically defined republics in the Soviet Union created the structural basis for ultimate disintegration of the Soviet Union.

Cultural and Cognitive Perspectives

Recent theoretical analyses emphasize both the cultural and cognitive components of social movements, suggesting that group identity is both an important mobilizing strategy and a consequence of mobilization. In particular, movements invoke one or more cultural themes of nationalism, rights of self-determination, expansion of human rights, and basic rights of sovereignty (Brubaker, 2004). Another line of argument within this cognitive tradition emphasizes the causal role of emotion in producing and escalating ethnic violence. In this view fear, resentment, and revenge play a key role in determining the conditions under which widespread ethnic cleansing and rioting occur (Horowitz, 2001; Petersen, 2002). Scholars from this tradition emphasize the importance of historical contingencies that seek to identify the particular historical outcomes that are shaped by broad cultural factors as well as idiosyncratic twists of fate.

An advantage of this view is that ethnic identity can be analyzed as the result (rather than the cause) of collective action. This insight opens up the possibility for studying how social mechanisms of contact, conflict, borrowing, and other forms of interaction cause new ethnic or racial categories to emerge. Interesting questions about the collective nature of conflict arise. For example, as group violence and revenge escalates on either side to a conflict, small-scale or individual skirmishes became redefined as events requiring a collective response. In analyzing forces escalating group conflict, scholars from the cognitive tradition emphasize the emergent properties of both identities and conflict.

Research guided by this tradition tends to focus on ethnic social movements that did occur, which limits the explanatory power of such studies. Another drawback of a purely cognitive perspective is that it is difficult to determine the causal ordering of emergent group identity and ethnic mobilization.

Globalization and the Internationalization of Ethnic/Nationalist Movements

Economic and political crises that once affected only local areas now have repercussions in vastly different and formerly unconnected regions and states. Since the advent of modern media, civil wars, terrorist acts, and acts by ethnic social movements have produced reactions across national borders. Taking an international perspective helps clarify how economic interdependence within states has reinvigorated ethnic politics.

Transnational Ethnic Social Movements

Transnational ethnic social movements are social movements that span multiple national borders, target forces of global integration, or are social movements that concern global-level issues (e.g., global environmental concerns). Regional associations such as the European Union (EU), Organization of the Petroleum Exporting Countries, North Atlantic Treaty Organization, and other supranational organizations promote interstate migration and decrease reliance of regions within states on the military and economic power of the nation-state. Multistate organizations also provide an audience for insurgent groups demanding new sovereignty rights (Koopmans and Statham, 2000). In this view, an increasingly dense network of international economic relations, exemplified by multinational corporations, growing trade and foreign investment, and supranational economic associations, will continue to produce more large-scale ethnic movements.

International Governmental Associations

One (perhaps unanticipated) consequence of the integration of the EU is that ethnic tensions have risen rather dramatically (Koopmans and Statham, 2000). Furthermore, as political and economic barriers have declined, labor (and capital) flow move more freely across states. However, one potential consequence of increasing flows of foreign workers across borders has been that new right-wing parties across Western Europe have mobilized sentiment against foreign workers. To the extent that the integration of the European Union has restructured local politics within European countries, the opportunity has arisen for ethnic politics on both sides of the immigration question. As a consequence, antiforeigner sentiment, nationalist political parties, and attacks on foreigners also appear to be rising in most Western European countries, especially in Germany, France, the Netherlands, and England (Koopmans and Olzak, 2004).

This perspective suggests that individual states will become less powerful in negotiations when confronting nonstate actors and/or transnational movements than in the past. As state economies and politics become more integrated, international

associations and events occurring outside state boundaries will become increasingly salient. It seems likely that as integration of the world's states (politically, diplomatically, and economically) proceeds, ethnic groups become less constrained by their own state authorities. The growing predominance of an integrated set of states ironically decreases the ability of any one state to direct all of its internal affairs. Moreover, highly integrated nation-states cannot simply repress, jail, or torture the ethnic challengers, without risking international condemnation, sanctions, and boycotts. Furthermore, neighboring countries may directly or indirectly finance campaigns of instability, using political refugees or exiles as mercenary soldiers. There is growing evidence on transnational environmental and human rights movements that supports these contentions (Olzak, 2006).

Diffusion of ideologies, resources, and personnel has accelerated these trends. Ethnic social movements occurring in neighboring countries have powerful diffusion properties, destabilizing or threatening nearby regimes. Sambanis (2001) argues that elite factions (or warlords) offering military and financial support from neighboring countries have played crucial roles in prolonging ethnic wars in Africa and Central Asia in recent years. Although it is difficult to study (because many of the transactions are clandestine and sources of data are unreliable), corruption feeds upon an increased flow of arms, mercenaries, and illegal drugs. It is likely that networks of local warlords also fuel ethnic wars (without state or international sanctions) in neighboring countries (Fearon and Laitin, 2003; Fearon, 2004).

Globalization and Ethnic Conflict

A global strategy offers arguments about forces of globalization that produce inequality, competition, and mobilization. Olzak (2006) holds that integration of a world economic and political system has encouraged ethnic fragmentation within states. It does so by increasing access of formerly disadvantaged groups to political resources, creating new political opportunities for mobilizing, and increasing levels of economic inequality in peripheral countries, which increases the potential for competition and conflict among groups within these states. As the world's states have become more directly linked through communication and media channels, information about inequality and claims for redress of this inequality has increased sharply. Thus, global forces of integration tend to crystallize and empower local level cleavages, increasing solidarity and heighten the capacity to mobilize movements challenging state authority (Olzak, 2011).

Global perspectives suggest another way that an ideology supporting human rights has accelerated the acceptance of an ideology supporting minority rights, especially ethnic ones. In this view, as the worldwide human rights movement gained momentum, claims for national sovereignty, group rights, and freedom became intertwined. In this view, as nation-states became linked together in networks of military and economic associations, national political boundaries weaken and political regimes become vulnerable to international and external challenges. The same forces that encouraged the diffusion of nationalism as an ideology also affect ethnic movements within and between state boundaries.

Military interdependence constitutes an obvious way that international relations affect conflicts within countries. Although such strategies are not new, superpowers arm and train ethnic and subnational groups in order to stabilize or in some cases destabilize regimes. The cases of rebellions financed and supported by transnational forces (on both sides of the struggles) in civil wars in Afghanistan, Nicaragua, Vietnam, Sudan, Iraq, and many other settings illustrate this point. If arguments suggesting a link between international networks and E/R/N movements are correct, then an increase in transnational processes could potentially weaken the viability of the nation-state as a main organizing strategy for territorial authority and control.

Pan-Ethnic/Religious Movements

Reactive movements are based upon pan-ethnic (or ethno-religious) claims that span national borders. Such movements often espouse ideologies that contrast with Western models of the so-called liberal state. In the contemporary era, some of these movements have been characterized as loosely connected by antimodernist claims that have a basis in both ethnic identity and religious fundamentalism. These movements espouse a form of identity politics (such as the wearing of head scarves), but they diverge from typical nationalist movements because they rarely express specific claims to govern specific territories. Whether or not such movements will continue to gain momentum remains an open question.

Evaluation of Various Perspectives

Many scholars analyze different types of E/R/N movements separately, by historical period, regional groupings, specific goals, or tactics. While it has become popular for scholars to claim that E/R/N movements are produced by a constellation of historically contingent factors, this strategy has hampered our ability to develop powerful explanations that identify some general mechanisms of social change. Yet other social scientists have demonstrated that there are substantial theoretical payoffs attached to analyzing the similarities across E/R/N movements. By paying attention to the commonalities among forms of ethnic and nationalist movements, we stand to gain more leverage over questions about how protest escalates and diffuses, or how spontaneous protests become transformed into sustained (or violent) social movements that challenge existing authority structures.

Approaches that seek to emphasize the continuities and discontinuities among social movements and their emergent forms allow cumulative and testable theories to be constructed and evaluated. In contrast, if multiple types of ethnic mobilization (from civil rights movements to ethnic civil wars) are analyzed separately by country, time period, and movement goals, it becomes impossible to know when to stop creating new categories and crafting unique explanations to cover each new occurrence of a nationalist event or ethnic campaign. Truly comparative work that seeks to build theories that can be falsified empirically holds far more promise than does a strategy that views each

movement as a unique and separate category. In the context of complex dynamics of transnational social movements, activists and organizations engage in an activity that engages and activates ethnic identity within nations. Such reactive movements can have reverberations to kindred or disaporic groups beyond a single nation. Understanding the commonalities among these forms in the context of a global system seems especially relevant.

Assessing the relative importance of various causal factors explaining ethnic movements over time is also hampered by the fact that ethnic and racial boundaries (and labels) often change over time. Answers to questions about the nature and trajectory of ethnic movements lie in conducting careful empirical analyses and comparisons of different kinds of events – ethnic, civil rights, national, religious, civil wars, and autonomy social movements of various kinds that share some (but not all) root causes.

Recent trends have taken these dynamics into account by emphasizing the emergence of a more densely connected global system. The globalization of social movements has led current research on ethnic and national movements away from a sole emphasis on internal features of states and toward the international context of collective actions. Clearly the internationalization of a world economy and political integration of organizational, diplomatic, and trade linkages have prompted us to reconsider previous assumptions that rest on stable characteristics of states. Research reviewed here depicts social movements that have produced strikingly similar social movements that share similar forms, goals, tactics, and ideologies. Thus theories that focus solely on the internal bases of discontent now seem short sighted.

A resulting network of economic and political ties based upon ethnicity potentially unites populations in different states but divides them against their own host states. As a consequence, ethnic mobilization at the global level provides fertile ground for new types of movements based upon national, ethnic, and other cultural identities. Such movements can be simultaneously local and international in scope. Because of this flexibility, E/R/N are able to shift strategies quickly and adapt to changing political and economic conditions. By turning to explanations firmly based on theories of international connections and processes, we may be better able to understand the emergence of new forms of nationalism.

Ethnicity and Educational Achievement

Abstract

This article provides an overview of the causal relationship between ethnicity and educational achievement. It sets educational achievement as a process in which culture is transmitted differentially and results in inequalities across ethnic and racial groups. This article summarizes key theoretical paradigms including genetic intelligence, cultural characteristics within a particular ethnic or racial community and social forces and structural attributes in students' school and classroom experiences, and most significant empirical research in each paradigm.

Introduction

In contrast to race referred to groups of people who have perceived differences and similarities in biological traits deemed by society to be socially significant, meaning that people treat other people differently because of them, ethnicity refers to shared cultural practices, perspectives, and distinctions that set apart one group of people from another. That is, ethnicity is a shared cultural heritage, whether real or imagined. The most common characteristics that discern various ethnic groups are ancestry, a sense of history, language, religion, ritual, and forms of dress. Ethnic differences are not inherited, but learned. Yet, in day-to-day life race and ethnicity are often viewed as inseparable because the social construction of a racial category, for example, Asian or Black, carries with it a host of cultural meanings. We choose ethnicity as a focus because perceived racial groups more often than not have a shared cultural heritage, whether real or imagined. More importantly, this article addresses educational achievement as a process in which culture is transmitted differentially and results in inequalities across ethnic and racial groups.

School education is neither socioculturally nor sociopolitically neutral. Through institutional arrangements and pedagogical practices, certain ethnic identity and its underlying values, beliefs, and characteristics are represented within education spaces, yet the cultural dimensions of other ethnic groups may be marginalized by education as 'minority' culture. As Pierre Bourdieu (1986, 1991) points out, in the concept of cultural capital, that the culture of the dominant group always possesses the legitimate and valued cultural capital in education sector, and thus prevents other cultures from obtaining any legitimacy in daily school life. Such process of cultural socialization in education, ultimately, yields the system of societal stratification beyond linguistic and cultural differences, implying that those coming from other cultural backgrounds will be sidelined in the struggle for academic achievement and later, social status.

Inequality on the basis of ethnicity occurs in both the developed and the developing world and has become a matter of international urgency. In any pluralistic society, scores of students from some racial/ethnic minority groups are not on a par with either those of mainstream students or those of students from other racial/ethnic minority groups. To ameliorate the educational problems is thus to ensure equitable access of underprivileged students to all levels of education (Coleman et al., 1966; Postiglione, 1999). Various explanations have been drawn on to account for ethnic students' educational achievement and attainment and most implicate the role of ethnicity. This article thus identifies important theoretical paradigms that explain ethnicity-driven discrepancy in achievement and summarizes most significant empirical evidence in each paradigm. It introduces its readers to three major theoretical standpoints that represent different schools of thoughts in the field of research including: genetic, cultural, and social/structural. However, the readers are expected to bear in mind that ethnic origin is not the solely contributory force to academic gap; and other factors made of race, socioeconomic status (SES) (*see* Socioeconomic Status and Academic Achievement), gender (*see* School Achievement as Moderated by Sociodemographic Status: The US Case), and ability, also cause discrepancy in achievement. This article, albeit aware of the significance of intersectionality, subscribes to the role of ethnicity in inequality of education.

Theoretical Explanations for Achievement Gap

Among the well-known theoretical models, genetic and cultural perspectives demonstrate the effects of home or community background as a set of 'inputs' that children bring with them to school on their academic outcomes, yet the structural explanatory model attributes race, ethnicity, and cultural factors as key social forces that predict educational processes, practices, and policies, which in turn produce variations in educational outcomes. The emerging theories are consistent in their affirmation of the significance of ethnicity being a necessary condition for academic achievement, but are divergent in their stances on the ways ethnicity impacts upon achievement. Of significance for the divergence is whether inherited and cultural characteristics directly influence students' learning and achievement in school, or innate traits guide educational policies, processes, and practices, the nature of which determines the ultimate learning outcomes.

Paradigm 1: Genetic Deficit Theory

Genetic deficit theory, also called 'biological determinism', associates gap in achievement with racial/ethnic groups'

 http://dx.doi.org/10.1016/B978-0-08-097086-8.92140-8

differences in cognitive abilities that arise from innate biological differences. This approach places race and ethnicity as static and relevant studies adopt intelligence quotient tests (IQ tests), and posit racial/ethnic patterns of genetic variation as a main determinant of one's intellectual capabilities over environmental and cultural attributes. Genetic deficit theory or biological determinism was a prominent explanatory paradigm in the 1960s, particularly in the US. Its advocates include Arthur Jensen, Richard Herrnstein, and Charles Murray. In 1969, Arthur Jensen, American educational psychologist, published an article entitled 'How much can we boost IQ and scholastic achievement?' in which Jensen advocates that IQ test is a scientific measure of intelligence, and 80% of a person's intelligence is solely dependent on racially heritable genes. He accordingly concludes that compensatory education of the US for less intelligent African-American children is ineffective and apparently has failed. Jensen's claim is supported by Hans Eysenck, a psychologist born in Germany and spending his professional career in the UK. Eysenck asserts that genetics is more determined by one person's cognitive ability than by environment. In his book of 1973 'The inequality of man', Eysenck writes: "The whole course of development of a child's intellectual capabilities is largely laid down genetically, and even extreme environment changes … have little power to alter this development" (pp. 111–112). Eysenck further suggests that Italian, Spanish, Portuguese, and Greek immigrants in the US are intellectually inferior and are in relevance to the populations in their countries of origin in Europe. The frame of reference has been utilized by the supporters of the 'New Right' in the US, who deliberately claim that government expenditure on education is unlikely to solve the problem of underachievement among genetically deficit student population. Today, the genetic paradigm continues to germinate within the academy as exemplified by Richard Herrnstein and Charles Murray's 1994 book 'The bell curve'. Using empirical statistical analysis, Herrnstein and Murray posit that the differences between 40 and 80% in intelligence between individuals are caused by genetic factors; 60% of the variation in IQ test scores between Black and White Americans accounts for differences in inherited intelligence between Blacks and Whites. They thereof come to the conclusion that racially inherited differences in IQ are a major factor predicting why some ethnic groups cannot excel in school.

Genetic deficit perspective, however, has attracted criticisms of not only its theoretical rationale, but its research methodology. Soon after the publication of 'The bell curve', the American Psychological Association's Board of Scientific Affairs responded to the increasing controversy around it in the statement that there is no certain support for racial differences and genetic hypothesis. In the edited volume 'The bell curve debate' (Jacoby and Glauberman, 1995), that involves 81 authors' writing comments on the book 'The bell curve', one of the authors Leon Kamin contends by using the separated twins as an example that the separated twins are always reared in similar environments, which demonstrates much more the observed similarities in IQ test scores. In addition to the contention that genetics cannot solely account for difference in intelligence, critics as well question the validity of intelligence based on IQ tests. For instance, Stephen Gould (1994) criticizes the four underlying assumptions made by Herrnstein and Murray ((1) Intelligence must be reducible to a single number. (2) Intelligence must be capable of rank ordering people in a linear order. (3) Intelligence must be primarily genetically based. (4) Intelligence must be essentially immutable) and argues that the assumptions are false and thus the entire argument based on them is false.

Paradigm 2: Culture-Relevant Explanations

Cultural Deficit Theory

Aroused by the thrust to eradicate poverty in the US and by the rejection of geneticists' argumentation, cultural deficit theory, also termed 'culture of poverty' or 'culture of deprivation', emerged during the early 1900s, and was prominent in the 1960s. This theory replaces nature with nurture as the main cause for school failure. Its theorists assume that some racial/ethnic groups do not experience a cognitively stimulating family environment and thereof their cultural attributes or practices are inferior and intellectually impoverished (e.g., limited outlooks toward the future, a lack of work ethic, low intellectual abilities, and other deficiencies such as early initiation to sex among children, female-headed households, or a limited interest in education, as identified by Stanley Eitzen and Maxine Baca Zinn in 2006), thus preventing them from achieving in school (e.g., Bereiter and Engelmann, 1966; Deutsch, 1967; Hess and Shipman, 1965) and resulting in culturally based cross-generational poverty (Lewis, 1959).

Cultural deficit theory, in spite of a highly ethnocentric view (e.g., Baratz and Baratz, 1970; Valentine, 1968), receives much attention in the community of education and it helps place the responsibility for school failure to minority children and their families (Ryan, 1976; Sleeter, 1993). For example, it is widely claimed that cultures or religions of some minorities such as Latinos in the US, Afro-Caribbeans in the UK, or Tibetans in China are inferior and in turn restrict the groups' possibilities of success in education. The explanation is compatible with the view that White working-class students' relatively low achievement arises from the cultural pathology of working-class people (e.g., Reay, 2001). As a frame of reference, cultural deficit model has its far-reaching significance in terms of the formulation in education policy and instructional practice that low-income populations and in specific racial/ethnic minority students at a disadvantage are required to overcoming cultural deficits caused by their families and communities in order to achieve in education. In the US, one of the representative policy initiations is the head start, a program launched in 1965 by the US Department of Health and Human Services, in order to alter the cultural attributes of low-income ethnic minority groups by the provision of comprehensive education, health, nutrition, and parent involvement services to low-income families and their children (Zigler and Styfco, 1996).

Cultural deficit paradigm flourished in the 1960s and today it continues to be a significant explanation for some racial/ethnic groups' underperformance in school and their subsequent limited mobility in society. For instance, in response to Herrnstein and Murray's work in 'The bell curve', Jencks and Phillips (1998) constitute the heredity-environment dichotomy and suggest that Black students' failure in

education is attributed to their family culture other than schools.

Cultural Difference Theory

In the late 1960s, cultural deficit theory was challenged by sociolinguistics, majorly by William Labov who criticizes ethnocentric cultural biases and argues that there is cultural difference in communication style between teachers and their minority students and "nonstandard dialects are highly structured systems…" (1969: p. 31). Rather than blaming either teachers or students, cultural difference or cultural compatibility/incompatibility model asserts that whether students excel or not in school reflects the cultural characteristics of the students, either compatible or incompatible with the dominant culture of schools; a lack of compatibility plays a vital role in school failure (e.g., Au, 1980; Davidson, 1992; Delgado-Gaitan, 1987; Erickson, 1987; Heath, 1983; Philips, 1972; Trueba, 1988; Vogt et al., 1987). Fredrick Erickson is a main advocate of cultural difference theory. Erickson pays attention to the 'micro' elements of classroom and points out that cultural difference theory provides 'a way of seeing classroom troubles as inadvertent misunderstanding – teachers and students playing into each other's cultural blind spots' (1987: p. 336). The home/school 'discontinuities'/difference model proceeds from the anthropological notion that minority students, families, and communities contain rich cultural and cognitive resources, termed by Moll et al. (1992) 'funds of knowledge'. The reason for the underachievement of the students is that mainstream schooling based on the prevailing culture espouses different values from those in minority culture.

Empirical research documents the variations in learning styles, expectations, languages, and interpersonal communication patterns between home and school, in particular between teachers and students as a source of limited success for ethnic minority students. For instance, Au and Mason's (1981) experimental study on native Hawaiian first graders illustrates a causal linkage between the cultural communication patterns of teaching and academic achievement. This study also supports the assertion made by Barnhardt and Heath that culturally responsive pedagogy, that is, accommodating to students' cultural norms, can not only reduce culture shock encountered by students, but affirm symbolically the culture of ethnic minority in school. Then cultural adaptation, in turn, will beget higher school performance. Other studies from the psychological view document the variations in learning styles and contend that racially and ethnically diverse students' learning results could be enhanced if their schooling experiences are able to resonate with their cognitive or learning styles (Boykin, 1986; Hale-Benson, 1986; Ramírez III and Castañeda, 1974; Shade, 1982).

Bourdieu's concept of capital that refers to the incompatibility of culture between home and school is particularly relevant to the cultural difference argumentation (Bourdieu, 1986; Bourdieu and Passeron, 1977; Lareau and Horvat, 1999; De Graaf, 1986). Cultural capital hypothesis suggests that privileged parents occupy a great deal of cultural resources that ensure their children's mastery of academic contents. Bourdieu views culture not as the traditional sociological term, but as a capital resource capable of generating 'profits' (Lareau and Weininger, 2003). He argues in an attempt to explain differences in achievement in France during the 1960s that the education system plays the role in reproducing and legitimizing the culture of the dominant classes (highbrow aesthetic culture including fine art and classical music) and in turn puts racial/ethnic minority students in disadvantage to navigate through the culturally biased academic knowledge and assessment. Among the empirical studies on the effects of cultural capital on educational achievement, De Graaf's (De Graaf, 1986; De Graaf et al., 2000) fieldwork presents the causal relationship between parental cultural capital and children's achievement. Using the Dutch educational system as an example for study, De Graaf highlights that the Dutch educational system values cultural elements, especially in terms of reading behavior that remains an important role to play in children's educational outcomes. De Graaf breaks the 'classical operationalization' of cultural capital, yet explains parents' cultural capital in terms of both the dominant highbrow cultural dispositions and linguistic and cognitive skills as human capital transmitted over generation. According to De Graaf, linguistic and cognitive skills, in specific reading abilities acquired at home contribute to children's human capital and in turn account for their success in education. Bourdieu in his writing of 'The forms of capital' (1986) develops types of capital, that include cultural capital, economic capital, social capital, and symbolic capital. In addition to cultural capital acquired in the home via exposure to a given set of family cultural practices, research evidence points out that social capital, namely, social resources offered by parents, tied to their high educational and occupational status positions, have important implications for educational outcomes. James Coleman's large-scale study of the influential factors for academic achievement articulates that there is a strong correlation between achievement and family background and environment (Coleman et al., 1966).

The cultural difference model implies that how the curriculum and the school environment act on such perceived differences is of importance with a view to decreasing academic gap. As a consequence, a call for multiculturalism in education appears alongside the 'ethnic revitalization' movements in many nation states during the 1960s and 1970s (including the civil rights movement in the US) with the goal of affirming the social, cultural, and historical experiences of students from diverse cultural backgrounds. Although multicultural education causes the warning that the celebration of diversity may undermine national unity and cohesion (Huntington, 2004; Schlesinger, 1998), multiculturalists such as James A. Banks argue that the European-American culture of schools invalidates the cultural experiences of students from non-European backgrounds and thus an infusion of multicultural education can be part of the solution to improving the educational achievement of students from diverse cultural backgrounds (Banks, 1999). One endeavor is to develop culturally relevant/responsive pedagogy that gives attention to the reflection of teaching toward a diversity of cultural practices (e.g., Ladson-Billings, 1994).

Cultural Ecological Model

Beyond the purely culture-centered explanations, Ogbu's cultural ecological model transforms the discourse toward a macro level of sociosystemic analysis in the investigation of school success or failure. As an America-based scholar, John Ogbu (1978, 1987, 1998) criticizes sociolinguistics-based cultural difference perspective and in his comparative research, he ties different minority groups' academic achievements in

the US not to school itself, but to the ways that they enter into the American society and receive schooling. He distinguishes between voluntary and involuntary minorities. Voluntary minorities such as Asian Americans are defined as immigrants who voluntarily come to the US in search of a better life. Involuntary minorities such as African-Americans or Native Americans as 'castelike' minority groups are those who have been incorporated into the US through slavery or conquest. Ogbu's cultural ecological explanation connects individual student's experience of schooling with the situation of the individual at the school and community level and in the wider society and its politics and economics. Empirical research evidence (e.g., Gibson, 1987) has shown that voluntary minorities are more likely to succeed educationally because they hold the meritocratic view and observe education as a means for success and upward mobility. On the contrary, involuntary minorities underachieve in schooling, which is seen as opposite to their culture and identities and do not believe the possibility of social mobility. It is argued that while involuntary families and community members hold negative beliefs toward school achievement, their children are less likely to engage in meaningful learning activities.

Cultural ecological model receives criticism because of its heavy emphasis on socioeconomic determinism without any room given to human agency. The success of Asian-Americans as voluntary immigrants in education is widely cited as evidence that involuntary minority students cannot acquire positive outcomes of education despite any special provision of bilingual or multicultural education. In addition, the model also fails to capture the variation within groups. Carla O'Connor's (1999) research questions perceptions of opportunity can predict academic engagement and she points out that it is dangerous to overgeneralize some populations of students and the heterogeneity or multiplicity within each group should be presented in the research of achievement disparity. For instance, even though involuntary minority groups, at large, do not indicate high performance in school, exceptions can be found and thus raise serious doubts about the adequacy of cultural ecological explanation. Moreover, according to this model, Asian-Americans have been seen as a monolithic group with shared educational and socioeconomic success. It ignores the fact that there is increasing disparity among Asian-Americans in educational and economic accomplishments (Gao, 2010; Kibria, 2002). Hence it may be dangerous to excessively emphasize cultural ecological explanation of educational achievement, in which school organization and teaching process actually play important roles.

Paradigm 3: Structural Inequality in Education

The structural/institutional paradigm of explanation for educational achievement emphasizes that race, ethnicity, and cultural factors within a particular family/community do not predict whether students learn and achieve in school, but as key social forces predict educational processes, practices, and policies that produce variations in educational outcomes. Whether educational institution reproduces or diminishes social inequality on the basis of race and ethnicity has been the most important research by sociologists of education. Proponents of the theoretical model shed light upon school funding, resources, curriculum and pedagogy, teacher expectation of students, tracking and ability grouping, and other school-level variables and contend that structural inequality of education may provide advantages of some racial/ethnic groups and marginalize or produce disadvantages for other groups. For instance, American sociologist Eric Hanushek criticizes Coleman's claim that differences in school resources are not indicators of student achievement, and schools cannot overcome differences in students' family background and SES. Hanushek (Hanushek, 1971; Rivkin et al., 2005) questions Coleman's examination on school quality by funding and teacher certification and teaching experience, instead, he argues that quality of teachers should be evaluated on the basis of student learning. Thereof Hanushek asserts that there are great differences across schools, which are not examined in Coleman Report, and schools certainly play an important role in student achievement and differences in teachers are extraordinarily significant in terms of achievement in school.

Structural explanations highlight the importance of equality of educational opportunity for the establishment of a meritocratic society where academic achievement and educational attainment are only relied upon students' academic merits rather than their ascribed racial/ethnic background. For scholars with the paradigm, to remedy or shorten the achievement gap is to critically examine the education system in order to counter any institutional racism (*see* Racism, Sociology of) and discrimination. Critical race theory (*see* Critical Race Theory) and critical pedagogy are actively promoted in order to make institutional injustice visible and challenge dominant power structures (e.g., Bell, 1976; Giroux, 1981). Relevant empirical studies range widely but mainly deal with three areas: school segregation, tracking, and teacher expectation (see Cook, 1983; Oakes, 1990; Rosenthal and Jacobson, 1968), and have important implications for educational policy and practice.

Unequal Access to School and Desegregation Policy

Although Coleman Report shows that school characteristics explain less of the variation in student achievement in comparison to family background, it evidently attests to a causal linkage between participation in predominately race-segregated schools and African-American students' lower test scores in the US. The report and other studies negate the possibility of segregated Black schools to provide the same quality of education as White schools and argue that access to White schools can ensure equality of educational opportunity for Black students. The research findings contribute to the implementation of desegregation policy and subsequently the change of student demography by bussing students in order to overcome the effects of residential segregation on public school demographics. Though desegregation policy in the US fell into dispute (see Clotfelter, 2004; Cook et al., 1984; Schofield, 1995), it has led to desegregation policy initiation in other regions of the world. For example, in Hong Kong new primary/secondary school admission policy takes racial/ethnic integration as a meaningful means to providing minority students with equal educational opportunities and ultimately to embrace them in the mainstream society (Gao, 2011).

Tracking System and Within-Class Ability Grouping

Empirical studies in the field of tracking and ability grouping examine a common educational practice, that is, assigning

students to different tracks and within-class ability groups, and explore the effects of tracking and ability grouping on academic achievement (Oakes, 1990). According to relevant research evidence, track assignments are based on both academic ability and by nonacademic factors because of the fact that racial/ethnic minority and low-income students are disproportionately placed in lower academic tracks. Researchers assert that higher tracks often offer a higher quality of teaching and instruction, and high-track students have opportunities to access to superior curriculum in a class environment, which is conducive to learning, and thus create unequal opportunities for students to learn. Statistical data have indicated the influence of tracking/ability grouping on academic achievement while controlling ability and prior achievement (e.g., Slavin, 1987). It is noted that students in higher tracks learn more and faster than those in lower tracks and the gap between high-track students and low-track students increases over the course of schooling. Hence, educational institution by its practice of tracking, does not ameliorate inequality of education, but maintain or even exacerbate educational inequality along the line of race or ethnicity. As a highly contradictory issue, tracking system has been criticized by some scholars under the consideration of equality of educational opportunity, but supported by others arguing its facilitation for teaching and instruction. At the current times, educational policy and practice mainly focus on how to modify tracking system in order to diminish its inequality while retaining its pedagogical benefits (Hallinan, 2001).

Teacher Expectation of Students and Labeling

Social-psychological processes of teacher expectation and labeling (*see* Labeling Theory, History of) account for race/ethnicity-based inequality of educational experiences in school. A body of research studies examines teacher expectation and its effects on students' behavior and academic achievement (Rist, 1970; Rosenthal and Jacobson, 1968). These studies report that teachers may have different expectations for students' performance and racial/ethnic minority students disproportionately receive the lowest teacher expectations. For example, Rosenthal and Jacobson (1968) in their study note that a teacher has lower expectation of children of 'darker skin color', or children whose mothers are 'on welfare', than of children of 'an upper-middle-class community'. Gillborn (1990) in his study of the educational experiences of Afro-Caribbean and South Asian children also points out that different racist stereotypes underlie White teachers' assumptions and expectations of Afro-Caribbean and South Asian students. In contrast to 'troublesome' Afro-Caribbean students, Asian students such as in Wright's (1992) research are always labeled by White teachers as students who have language problems and thus are excluded from class discussion. Teacher expectations ultimately create a self-fulfilling prophecy and greatly impact on student learning and achievement. The rationale behind is that students who are believed by teachers to have high ability tend to have more frequent and positive teacher-student and peer interactions and receive more attention from teachers that are conducive to learning. Intervention research and educational programs such as status expectations research are undertaken in order to raise racial/ethnic minority students' status in order for them to achieve more equal classroom participation with greater self-esteem.

Conclusion

This article outlines educational inequality in relevance to ethnicity. In the previous half century, a central concern in the sociology of education has been the relationship between educational inequality and societal stratification. Two traditional views in the field – structural functionalism and conflict theory – clarify this relationship in different ways. For the structural functionalists (e.g., Durkheim, 1969), the society is meritocratic and fair competition for society's resources is necessary for upward mobility. Equal opportunities to compete should be available to all persons of a society regardless of their social origin or other ascribed backgrounds, and inequality in the educational outcomes is seen as beneficial to the function of society. In comparison, Marx's (see Bowles and Gintis, 1976) conflict theory does not see fair competition as viable because ascribed backgrounds of individuals disadvantage certain people, and turn to the distribution of educational resources and rewards to address inequality. Conflict theorists question the ability of the education system to eradicate inequality and argue that a fairer and more efficient system is needed. It is thus important to note that the concept of ethnicity is not static so that the issue of education and ethnicity is relatively complicated and any explanation for achievement gap has to be proceeded with caution and appropriation to certain societal contexts, where either functionalism or conflict view may play a more important role. Given the ongoing challenges regarding educational stratification, communities, families, and schools are required to collaborate with each other so as to provide sufficient resources and supportive learning environments, in which ethnic minority students' academic needs can be met. The debate on the influence of ethnicity on student's educational outcomes will continue into the twenty-first century under the promotion of No Child left Behind.

Ethnicity and Ethnic Groups: Historical Aspects

Mathias Bös, Leibniz Universität Hannover, Hannover, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The term ethnicity is used for a broad spectrum of groups in history. Ethnic community building is used to foster solidarity in macro-group structures, to legitimize social inequalities by descent, and to fulfill individuals' need for belonging. In the social sciences there is a growing consensus that ethnicity is socially constructed and historically contingent, but that many people perceive it as an important, unchangeable part of their identity.

Is 'Ethnicity' Ancient or Modern?

Some argue that ethnicity is as old as human kind. Hittites, Luvians, Minoans, Canaanites, Amorites, Elamites – these are just a few examples of ethnic groups that Anthony D. Smith lists as important in the political world of the ancient Near East 2200–1700 BC in his book *The Ethnic Origins of Nations* (1986). In this perspective ethnic groups have been a significant factor in the rise and fall of political powers in the history of Europe and the Near East for thousands of years.

There is, however, a totally different view that sees ethnicity as a typically modern phenomenon. This argument is expressed most forcefully by Nathan Glazer and Daniel P. Moynihan, in their seminal reader *Ethnicity: Theory and Experience*.

> We are suggesting that a new word reflects a new reality and a new usage reflects a change in that reality. The new word is 'ethnicity', and the new usage is the steady expansion of the term 'ethnic group' from minority and marginal subgroups at the edges of society – groups expected to assimilate, to disappear, to continue as survivals, exotic or troublesome – to major elements of a society. … [T]here is something new afoot in the world, and…we may label it 'ethnicity.'
> (Glazer and Moynihan, 1975: p. 5)

In one view ethnicity is ancient; in the other it is modern. This contradiction might be due to the fact that both views focus on different kinds of ethnicity. Smith sees ethnic groups as geopolitical groups. He observes the long history of often violent ethnic conflicts associated with group memberships and forms of belonging. Glazer and Moynihan are talking about the group formation processes in times of migration, urbanization, and globalization. For them ethnicity is something that emerges within the political system of modern multicultural societies. Reflecting on the historical aspects of ethnicity Randall Collins argues:

> Ethnicity is an intrinsically messy topic because the historical processes that produce it are intrinsically messy. Our analytical problems stem from the fact that ethnicity is always a distorted concept, an attempt to impose a pure category on a social reality that is not at all pure.
> (Collins, 1999: p. 78)

Brief History of the Vocabulary of Ethnicity

The adjective 'ethnic' came into use in English during the fifteenth century, denoting characteristics of groups that are not considered Christians or Jews. At that time the term ethnic was roughly equivalent to words like heathen or pagan. In the nineteenth century the adjective ethnic was increasingly used in its modern meaning as 'pertaining to or having common racial, cultural, religious, or linguistic characteristics, esp. designating a racial or other group within a larger system' (*The Oxford English Dictionary* 1989). The word ethnic derives from the Greek term **ethnos** and the corresponding adjective **ethnikos**. The word denoted any nonspecific collective, like warriors or bees. Later it was mostly used in respect to foreigners and collectives outside the city-state, sometimes with a derogatory connotation; it roughly translates into what in English today is called a nation.

The term 'nation' derives from the Latin word **natio**, denoting a group of common descent quite similar to breed or stock. In English, nation was used in respect to foreign groups, as in 'Indian nations' during the times of colonial America. But it meant other groups of a kind as well, for example, lovers or school boys. Increasingly the meaning shifted from an emphasis of common descent or kind to processes associated with political groups. Today one of the main differences between ethnic group and nation lies in the fact that the latter implies much more strongly the idea of political self-determination and the demotic element of group action than the former. The meaning of nation moves closer to that of a demos, a term which in the social sciences refers to the political aspect of a people. The Greek term **demos** was used for the common (free) people in a city-state. In the nineteenth century the word demos was occasionally used in English to refer to groups which act together to influence their political destiny, like in the 'Celtic Demos'.

The Greek world had a quite complex structure of ethnic groups such as Dorians, Ionians, Aeolians, and Achaeans (Hall, 2002) and many Greek authors like Herodotus described people in a way we would call ethnic today. Descriptions of ethnic groups are often found in Judeo-Christian European historical texts, but the social scientific concept 'ethnic' is modern. It was only at the beginning of the nineteenth century that the term ethnic became increasingly popular in the social sciences, where 'ethnological studies' set out to examine

 http://dx.doi.org/10.1016/B978-0-08-097086-8.62015-9

'peoples' with different customs, religions, or appearances (Gabbert, 2006). From the end of the nineteenth century onward, the adjective ethnic was also used to describe minorities within a larger political unit. Within North American and Western European societies, immigrant groups and minorities were often called 'ethnic communities'.

English lacks a noun corresponding to the adjective ethnic, like the French 'ethnie', so the expression ethnic group or ethnic community is used in the social sciences to refer to a group of people with the property of being ethnic. The term 'ethnic community' was commonly used for immigrant groups or minorities until the middle of the twentieth century (Ware, 1937[1934]). The word 'ethnicity' is even younger. Having come into use at the beginning of the 1940s (Sollors, 1996), ethnicity refers to the characteristic of a person or a group. This stands in contrast to the term race that can be used to refer to a group and to the characteristic of belonging to a group social defined by biological markers.

The term 'race' is used in the same context as ethnic groups, denoting geopolitical macro-group structures or societal minorities in everyday life and in the social sciences. Like ethnic group, race is a comparatively new concept. Its etymological origins are in Spanish in the times of the Spanish inquisition. **Raza** basically meant a common stock of humans or animals, or simply a status group like nobles. During the nineteenth century race acquired a narrower meaning, referring to a group that shares a set of biological characteristics, as in 'human race'. Biological characteristics were also used to form subdivisions in human kind; one of the first taxonomies by J.F. Blumenbach (1865[1795]) used skin color and conformation of the head to characterize five races: American, Caucasian, Ethiopian, Malay, and Mongolian. Racial typologies were used to define groups of human beings assuming genetically based biological differences as congruent with differences in culture and character between human groups. Genetically based biological differences refer to the assumption that differences of races are based in genomic inheritance and emphasize the biological aspect of descent. The word genetically stems from the Greek **genos** for family, house, lineage, or species. The idea of race as a hierarchy of genetically determined human cultural groups lies at the very hard of racism (Hirschfeld, 1938). One of the reasons for the use of the term ethnic group in the social sciences was the attempt to substitute the strong biological meanings of race with a term that emphasizes the more flexible nature of differences between groups of assumed common ancestry (Fenton, 2010).

Whether the terms race and ethnicity refer to the same social phenomenon is open to discussion, but typical phrases like 'race and ethnic studies', 'race and ethnic relations', or 'racial and ethnic disparities' somehow imply that they belong to a common set of social facts. Race and ethnicity are today considered as forming an important part of identity. Identity refers to the sameness of a person or group with itself over time and to characteristics that differentiate a group or person from another. In the social sciences, the term identity came into broader use at the same time as the word ethnicity. The two terms share the same ambivalence because they denote the need for belonging and autonomy (Gleason, 1996[1983]).

The word ethnic identity refers on the one hand to that what makes a person or a group a stable unit in time with characteristics deeply rooted in the biography of the individual or the history of the group, something that is difficult or even impossible to be changed. A person from the German state of Bavaria may consider himself or herself Bavarian in respect to food, clothing, or German dialect and considers these preferences as authentic and important. On the other hand ethnic identity refers to that which makes a person or group special or different from others. Traveling through Europe, this very same Bavarian can self-describe as a German when talking to a Frenchmen; while discussing the political situation with a New Yorker, the Bavarian can position himself or herself as an European. In this respect ethnic identity is something highly situational, which depends on the relations to other groups and persons in a given situation, something that can change often.

Approaches to Ethnic Groups and Ethnicity: A Sample

Since the nineteenth century, the social sciences have developed numerous approaches to the study of ethnic groups and ethnicity. The following sample of perspectives is no attempt to give a full overview. It focuses on those approaches – largely from sociology, political science, and cultural anthropology – which have either made a historically important contribution to the social scientific study of these concepts and/or which are still important to understanding ethnicity as a social phenomenon today.

For the evolution of a social scientific perspective on ethnic groups and ethnicity three scholars were particularly important, although they never or only rarely used the term ethnic group: Sumner, DuBois, and Weber.

William Graham Sumner (1840–1910) held the first professorship in sociology at Yale. His work *Folkways* (1907 [1906]) analyzes what in everyday language is often meant when one talks about ethnic groups. Sumner emphasizes the common traditions, a common way of life, a shared culture, and a group's myth of common ancestry as an important basis for group solidarity. In his book he synthesizes the huge corpus of ethnographic literature of his time and compares a wide range of groups, especially groups that he calls 'primitive people' around the world, depicting their differences in customs. To describe hostile sentiments in the in-group toward out-groups he coined the word ethnocentrism as the root for patriotism and chauvinism, and a main cause of intergroup conflict, even wars. Sumner was convinced that these ethnocentric preferences were something learned as a child, but he held a quite social Darwinistic view when it comes to the power structure between different groups.

William Edward Burghardt DuBois (1868–1963) was a sociologist, historian, and civil rights activist who devoted his whole scholarly oeuvre to the analysis of Africans and African-Americans as groups of common heritage and ancestry (DuBois, 1940). W.E.B. DuBois' sociology of ethnic or racial groups as macro-group structures is important for the history of the social sciences because he analyzed the complex structural causes of group solidarity. Summarizing his large opus under this respect, ethnic or racial group solidarity can be caused on three levels: (1) Ethnicity or race forms an important part of an individual's social identity. Here group membership is socially defined by common ancestry, common historical destiny, and

specific cultural expressions. (2) Ethnic or racial groups constitute a structure of social inequality. DuBois emphasizes the often coercive character of those groups and their institutional settings like family, neighborhood, church, work, and associations. (3) Ethnic or racial groups are a part of the macro-group structure in every society that is constituted as a nation-state and the world system. Here ethnic or racial groups are a part of the global power structure and are a crucial factor in processes of colonization, migration, and nation building (Bös, 2008).

The first full-fledged definition of an ethnic group was developed by the sociologist and political economist Max Weber (1864–1920):

> We shall call 'ethnic groups' those human groups that entertain a subjective belief in their common descent because of similarities of external habitus or of customs or both, or because of memories of colonization and migration; this belief must be important for the propagation of group formation; conversely, it does not matter whether or not an objective blood relationship exists. Ethnic membership (Gemeinsamkeit) differs from the kinship group precisely by being a (believed-in) membership, not a group defined by actual social action, like the latter. In our sense, ethnic membership does not constitute a group; it only facilitates group formation of any kind, particularly in the political sphere. On the other hand, it is primarily the political community, no matter how artificially organized, that inspires the belief in common ethnicity. This belief tends to persist even after the disintegration of the political community, unless drastic differences in the custom, physical type, or, above all, language exist among its members …
>
> (Weber, 2007[1920]: p. 301)

For Weber the membership in an ethnic group is based on the subjective belief in group membership regardless of any 'objective blood relationship'. Furthermore he argues that subjective beliefs in common descend follows from factors like similarities in customs or historical memories of colonization and not the other way around. Historically, ethnicity is not the cause of cultural differences but a subjective interpretation of group relations based on existing differences. Technically speaking in the language of modern social sciences, being ethnic is the dependent not the independent variable. Or using Marx's classical distinction between class 'in itself' and class 'for itself', there is only an ethnic group for itself and nothing like an ethnic group in itself. There is no such thing as an ethnic position in the social structure independent from the perception of an actor, being a member of an ethnic group is always a conscious and active process. Instead, ethnic groups are caused by social structures and they promote social structures. The propagation of group formation usually goes hand in hand with ethnic closure, that is, the use of ethnicity by a group to monopolize life chances (Bös, 2004).

Besides a few pages on ethnic groups in 'Economy and Society', Weber did not use the concept of ethnic groups in his social analysis. But many authors implicitly or explicitly refer to his pathbreaking conceptionalization. He also straightforwardly rejected the biological notion of race as an explanation of historical processes in the social sciences. Like ethnicity, Weber saw race as a cultural construction; in fact, he conceptualized race as a subtype of ethnic groups characterized by socially constructed physical markers.

The interactionistic approach to ethnic groups, developed by US-American sociologists like Robert Ezra Park (1864–1944) and William Isaac Thomas (1863–1947), was influenced by Weber and, more strongly, by the work of the German sociologist Georg Simmel (1858–1918). For Park and Thomas society is a huge web of interactions between individuals and between groups. Epitomized by Simmels' famous 'web of group affiliations', individuals are defined by their memberships in a whole set of different groups, these multiple memberships are the structural condition to become an autonomous individual.

The definition of a situation by the actor himself or herself is the key to understanding his or her action; as W.I. Thomas famously formulated, when men define a situation as real, it yields real consequences. What it means to define a situation in reference to ethnic group membership can be analyzed, for example, in letters from immigrants to friends and relatives in their country of origin (Thomas and Znaniecki, 1958[1918]). For immigrants, ethnicity is something newly created in the immigration situation of the host country. The social structure of the host country plays an important role in this type of ethnogenesis. Societies develop social forms like the 'marginal man' (Park, 1928) or the 'stranger' (Simmel, 1983[1908]) as stable social meaning structures that govern the internal logic of a definition of the situation. But besides this radical actor orientation, especially Park tended to develop sweeping historical generalizations of intercultural processes like the race relation cycle: contact, conflict/competition, accommodation, and assimilation. He considered these stages to be universal; all racial or ethnic groups go through this cycle when they come into contact with a majority.

At the beginning of the last century it was quite common for social scientists to see world history as the consequence of a power struggle between human races, where lower races were doomed to fail. The battle against this form of scientific racism was primarily fought by cultural anthropologists like Franz Boas (1858–1942). His two main arguments against scientific racism were statistical and historical. Statistically, the distribution of characteristics like intelligence between ethnic or racial groups may show a small difference in means between groups, but they nevertheless overlap extremely so that a highly intelligent individual of one racial group has a high statistical chance to be more intelligent than the average person of another group. This means that a small statistical difference in the means of two distributions cannot legitimize the different treatment of these groups, for example, in the education system. Furthermore Boas argued that even if there are statistical differences, for example in bodily features between groups, these differences tend to equalize within a short time span, if these groups live in the same social and environmental conditions.

The other main line of argumentation advanced by cultural anthropologists was historical. Over time, all ethnic groups and races have made important technological and social contributions to the evolution of mankind. This historical insight undermines the assumption of the evolutionary superiority of one group over the other. At the end of the interwar period, the key assumptions of scientific racism were proven wrong: there are no genetically based cultural differences between groups that are socially meaningful; the alleged evolutionary-based

hierarchy between races is only a myth, and 'race mixture' is no indicator for the decline of a racial group.

The falsification of racist ideas led social scientists to abandon the term race from their theoretical vocabulary. This point was eloquently made in Ashley Montagu's book *Man's Most Dangerous Myth: The Fallacy of Race* (1997[1942]). Later on (1951) Montagu was one of the main authors of the UNESCO statement against the use of the word race in politics or science. This position was also seen as a lesson learned from the role of the ideology of race in the hideous crimes of Nazi Germany. Whereas cultural anthropologists adopted this stance, especially Anglo-Saxon sociology kept using the term race as a scientific concept.

The best expression of the American sociological perspective on ethnicity after World War II is surely Warner and Srole's book *The Social Systems of American Ethnic Groups*, which was published in the Yankee City Series:

> The future of American ethnic groups seems to be limited; it is likely that they will be quickly absorbed. When this happens one of the great epochs of American history will have ended and another, that of race, will begin. Paradoxically, the force of American equalitarianism, which attempts to make all men American and alike, and the force of our class order, which creates differences among ethnic peoples, have combined to dissolve our ethnic groups. Until now these same forces have not been successful in solving the problem of race.
>
> (Warner and Srole, 1945: pp. 295–296)

In this book Warner formulated the American relational model of the terms 'race' and 'ethnicity'. For him, the important difference is that race refers to socially recognized bodily features, with ethnicity forming a kind of cultural subdivision of races. This can be called Model I: societies are divided into races that may be further divided into ethnic groups. The alternative, Model II, depicts societies as divided into ethnic groups, only some of which are 'racialized'. This is the Weberian model in which 'ethnicity' is the general term, and in some cases one sees biological features used as markers for ethnic groups.

Milton Gordon's pathbreaking study *Assimilation in American Life* (1964) formulated two central arguments: ethnic group formation within society is closely connected to economic factors and assimilation is always a complex, multidimensional process. The economic status of a group is often the prime factor that determines its lifestyle and its attitudes. Since the congruency between ethnic groups and classes can be observed quite often, Gordon coined the term ethclasses. Even more importantly he conceptualized the multidimensionality of ethnic group relations. He formulated seven dimensions: (1) Acculturation: the adoption of cultural features like language or customs. (2) Structural assimilation: the participation in institutions of the host society, especially in the economy. (3) Marital assimilation: intermarriage and 'mixed families' as important process of assimilation in the private sphere. (4) Identificational assimilation: the minority identifies with the values and aims of the surrounding society. (5) Attitude reception assimilation: the reduction or absence of prejudice. (6) Behavior reception assimilation: the reduction or absence of discrimination. (7) Civic assimilation: the inclusion into the system of political power. These dimensions are not necessarily synchronous; people can be integrated, for example, on an identificational dimension, but disintegrated in a structural dimension. There can be a largely acculturated and structurally integrated ethnic group, but still a high level of discrimination.

A significant refinement in understanding ethnic group processes was Barth's (1969) concept of 'ethnic markers'. The main structural problem of an ethnic group is border maintenance: For every ethnic group it is important to know who belongs to the ethnic group and who does not. Cultural markers – including language, hairstyles, or food preferences – can serve as indicators of membership, as ethnic markers. This kind of ethnic differentiation is largely independent from other cultural patterns of the ethnic group. More often than not, cultural patterns are quite similar between ethnic groups. As already stated in Weber's definition, the propagation of ethnic community building can be based on many other factors than cultural differences. One case in point is the power conflict between different groups in former Yugoslavia and the increasing ethnicization of groups like Serbs and Bosnians.

Given its reflexive nature, ethnicity is always a cultural phenomenon, but ethnicity is not the same as culture. Culture encompasses the meaning structure and the praxis of human beings in their material and nonmaterial aspects. In the ideal typical case of a totally isolated human group, culture might be congruent with the borders of a (protoethnic) group, but in real life, owing to the diffusion of things, ideas or common traditions, culture is never limited to a single group. Ethnic groups, especially if they live close together, mostly share a huge amount of cultural features, ethnic markers often amount to that what Freud once called the 'narcissism of minor differences'. However, from the perspective of an actor, especially in highly emotionalized conflict situations, all acts and things can be ethnicized. For the ethnic mind everything becomes ethnic.

The fact that ethnic groups are primarily defined by ethnic markers and not by their 'cultural content' is one of the reasons that ethnic group formations are so flexible over time. The concept of symbolic ethnicity (Gans, 1999[1979]) elaborates exactly on that point. In studying the Jewish community in the USA, Herbert Gans observed that some ethnic cultural features (e.g., how to observe the Sabbath) changed to fit in the way of life of the majority. These changes do not weaken, but strengthen the emotional attachment to the community. In such a case of symbolic ethnicity, ethnic group formations fit structurally into society and serve as an important identity resource.

The old preoccupation of ethnic research with huge comparisons was revitalized again in the 1980s and 1990s, for example, in Daniel Horowitz's *Ethnic Groups in Conflict* (1985). The book compares deep ethnic conflicts in states in Asia, Africa, and the Caribbean that became independent after World War II. Here the focus of analysis shifts away from the assumed nature of an ethnic group to ethnic relations. Horowitz shows how the social form of ethnic conflict gets its own, often violent dynamic when a conflict system is ethnicized. In postcolonial situations elites or interest groups often promote the idea of ethnicity in order to pursue their interests. These processes were analyzed by Brass (1991) in his book *Ethnicity and Nationalism: Theory and Comparison* that focuses on cases in India and the

former Soviet Union. He emphasizes the fluid nature of ethnic macro-group structures and political situations, where elites struggle over resources and for political control.

In nation building processes in general an integral part of the ethnicization process is the invention of traditions (Hobsbawm and Ranger, 1983). Like ethnic groups, nation-states reconstruct their history, describing their contemporary political unit as the logical product of a series of historical events: in the case of France, for example, this constructed narrative starts with the Gauls 1000 BC through the 'golden age' under Charlemagne onto the French revolution and Napoleon. Only very few inhabitants of modern France would find it especially appealing to live under the material and cultural conditions like the Gauls, nevertheless many may consider themselves as a part of a common historical collective.

Especially literature that discusses the relation between ethnic groups and power structures, apply rational choice theory to explain ethnic mobilization (Hechter et al., 1982). This seems counterintuitive since ethnicity epitomizes a social phenomenon that is dominated by emotions and, sometimes, irrational behavior. Nevertheless one can make the argument that ethnic behavior is the result of strategic action, through which people pursue their own interests. This line of thinking connects to the idea, already put forward by Weber, that the propagation of ethnic community building is usually associated with an attempt to monopolize life chances.

An important part of the cultural turn in the social sciences in the 1980s was the increasing interest in the history of ethnicity, be it in social and cultural anthropology (Chapmann et al., 1989) or in sociology, as in the sociology of literature (Sollors, 1986) or in race and ethnic relations (Waters, 1990). All of these approaches try to describe and conceptionalize the ambivalences of ethnicity; its flexible yet rigid nature, its coercive yet emancipating character. The introduction of concepts such as diaspora and trans-nationalism further advanced the theoretical debate about race and ethnicity. These concepts, sometimes framed in terms of globalization, advanced the interpretation of the history of group formation outside the nation-state (Gilroy, 1993; Kivisto, 2001).

One important recent contribution to the theorization of the historical aspects of ethnicity is Jan Nederveen Pieterse's book *Ethnicities and Global Multiculture: Pants for an Octopus* (2007). Today ethnic community building processes result from the hybridization of Asian, African, American, and European cultures. According to Nederveen Pieterse, ethnicization can have different structures: domination, enclosure, competition, and optional. He even argues that in a time of optional ethnic identities within global multiculture the change of the social form 'ethnicity' is so deep that we can speak of postethnicity.

Conclusion

In the plethora of voices in the social sciences ethnicity is something old, something new, or something we are nearly over with, but the concept nevertheless serves as a focal point for new creative research and for intriguing theoretical developments.

The emphasis in this article is mainly on English-speaking Western European and North American approaches to ethnic groups and ethnicity. Like most subfields of the social sciences, research on ethnic groups has distinct national histories in respect to empirical research and theorizing. Especially for the USA, it is fair to say that the history of social scientific research on ancestry-based groups is more a history of race than of ethnicity. This fascination with race directly reflects the focus of societal discourses: a fixation that Gilroy (2000), among others, deems increasingly problematic.

In the social sciences there is surely a growing consensus about ethnicity: although perceived by many people as an important, unchangeable part of their identity, scholars see ethnicity as socially constructed and historically contingent. As long as solidarity in macro-groups is produced through tradition, as long as social inequalities are legitimized by descent, and people feel the need for belonging, researchers will not run out of material to which the concepts of ethnic groups and ethnicity can be applied.

Abstract

This article approaches migration and ethnic diversity issues from the social psychology of intergroup relations. From an intergroup-relations perspective, minority and majority experiences of ethnic diversity are interdependent; and they are jointly shaped by the prevailing diversity climate in a particular society. Accordingly, the article consists of three main sections. The first section sketches different patterns and policies of migration and ethnic diversity at the societal level. The second section discusses majority attitudes in European societies. The third and last section shifts focus to minority experiences of acculturation against the backdrop of generally restrictive diversity climates in Europe.

Immigration and ethnic minority issues pose major social, political, and intellectual challenges to contemporary Europe. European societies are coping with rapidly diversifying immigration streams. New arrivals include asylum seekers, refugees, sojourners, and documented or undocumented immigrants from all over the world. Additionally, growing numbers of European students and highly qualified professionals are living and working outside their countries of origin within the European Union. While the center and south of Europe are more recent destinations, in the northwest of Europe the second generation of post-1965 immigrant workers and (post)colonial immigrants, is coming of age. Meanwhile, new immigration into the northwest of Europe continues. Across Europe, most countries have extended civil rights to immigrant minorities, and some have developed targeted policies to include immigrant minorities. Yet, immigrant–host relations in European societies are generally unequal and often tense. Especially, Muslim minorities are facing widespread prejudice and discrimination (Heath et al., 2008).

Against this background, social psychological research in Europe has addressed the key question when migration and ethnic diversity are divisive issues; and when they are positive forces in the lives of individuals, groups, and society at large (Chryssochoou, 2004). This article reviews research on ethnic diversity among immigrant minorities in Northwestern Europe. It does not cover other sources of ethnic diversity in an enlarged European context, such as the presence of nonimmigrant or 'indigenous' minorities with either national (e.g., ethnic Hungarians outside state borders) or ethnic status (e.g., Roma and Jewish minorities in Hungary). For the purpose of this article, immigrant minorities include the first generation of immigrants proper and their native-born offspring, the so-called second generation. Host majorities refer to a nonimmigrant reference group of native-origin citizens in the same city, school, or country. The terms majority and minority culture or identity will be used to distinguish the dominant national cultures and identities of the receiving countries from the heritage cultures and the distinct ethnic or religious identities of immigrant minorities. Multiculturalism refers to the acceptance and valuing of ethnic diversity and to inclusive diversity policies that accommodate minority culture and identity.

With its great variety of national and ethnic cultures and institutional arrangements, Europe constitutes a natural laboratory for studying the different ways in which societies organize immigrant–host relations. Varying diversity patterns and policies across Europe give rise to different social and psychological realities for both immigrant minorities and host majorities. Parallel and largely separate research lines in social psychology have studied (1) sources of ethnic prejudice and ways to reduce prejudice among host majorities, and (2) acculturation processes and their consequences for the success and well-being of immigrant minorities. Combining both research lines, this article takes an integrative approach of diversity research from the social psychology of intergroup relations (Brown and Zagefka, 2011). From an intergroup-relations perspective, minority and majority experiences of ethnic diversity are mutually interdependent; and they are jointly shaped by the prevailing diversity climate in a particular society (Phalet and Kosic, 2006). Exemplary findings will be organized theoretically around a multilevel and multigroup approach of migration and ethnic diversity. A multilevel approach connects psychological experiences of ethnic diversity in intergroup encounters (at the microlevel) to the ways in which societies organize and represent diversity and intergroup relations (at the macrolevel). In addition, a multigroup approach distinguishes between, most often asymmetrical, minority and majority group perspectives on ethnic diversity and intergroup relations.

This article consists of three sections. The first section sketches different patterns and policies of migration and ethnic diversity at the societal level, and discusses their implications for immigrant–host relations. The second section draws on prejudice research to discuss generally restrictive public attitudes in European societies, and how they relate to majority experiences and representations of ethnic diversity. The last section shifts focus to minority experiences of acculturation against the backdrop of less welcoming diversity climates and majority attitudes in Europe.

Diversity Patterns and Policies in Europe

Ethnic Diversity and Inequality

In Western Europe, issues of ethnic diversity have been mostly concerned with the incorporation of immigrants from outside Europe and their descendants. In addition, European enlargement and the uneven burden of the current economic crisis within the European Union, have contributed to increasing numbers of so-called free movers in Europe, including many students and professionals. Different origins, motives, and destinations of immigrants have implications for ethnic diversity patterns in European societies. Across Europe, children of immigrant workers from less developed countries or regions are facing significant socioeconomic disadvantages and widespread ethnic prejudice and discrimination. For instance, the first generation of Turkish and Moroccan 'guest workers' were recruited in the 1960s and 1970s mainly from less developed rural areas within Turkey and Morocco to be employed in unskilled industrial jobs in Europe. From the 1980s onward, family reunion and family formation enabled their permanent settlement and the establishment of major immigrant communities. In the same period, the post-industrial transition of European economies was pushing them out of a shrinking industrial sector into massive unemployment and economic inactivity. The first generation has passed their inferior group position at the bottom of the stratification heap on to the next generation, as evident from persistent educational disadvantage, high poverty rates, residential segregation in underprivileged urban areas, high risks of unemployment and inactivity, and restricted access to stable and well-paid jobs. In spite of antidiscrimination directives in Europe and legislation in most Western European societies, there is hard evidence of ethnic discrimination, for instance, in the labor market (Heath et al., 2008). Finally, the second generation has become a prime target of public hostility against Muslim communities in European societies (Voas and Fleischmann, 2012).

Migration and Integration Policies

In historical immigration countries, such as the United States and Canada, immigrants and their offspring are an indispensable part of the historical process of nation formation. In contrast, the nations of 'the old Europe' face the challenge of redefining and opening up their historically rooted national identities and institutions to immigrants from diverse ethnic and religious backgrounds (Phalet and Kosic, 2006). Most states in the northwest of Europe have gradually and selectively extended the civil and social rights that used to be the exclusive entitlements of the dominant national group to immigrants. Moreover, most have developed targeted social policies that converge on some variant of immigrant integration as a middle ground between multiculturalism and assimilation. In South and Central European countries where mass migration is more recent, diversity policies are less developed and more piecemeal. Under the umbrella of 'immigrant integration,' different countries are in fact reproducing and simultaneously reinventing their particular histories of nation building (Phalet and Kosic, 2006). Accordingly, countries differ in the (restricted) access of immigrants and their children to legal residence and national membership, in their protection from direct and indirect discrimination as well as in their social policies to promote equal opportunities in schools and in the workplace, and full participation in civil society and in politics (MIPEX, 2010). Overall, integration policies in the northwest of Europe range from assimilation, when minorities are required to give up their ethnic ties and traditions to become full members of the receiving society (e.g., in France), to some variants of multiculturalism, when multiple ethnic and national cultures and identities are accepted and valued (e.g., in Sweden, and until recently in the Netherlands).

An illustrative example is the case of national differences in the institutional incorporation of Islam in Europe. As distinct from a North American conception of freedom of religion as 'equal liberty' for all, European principles of 'religious tolerance' are premised on privileged relations between states and established churches; and they do not usually require full recognition of all religions (Fleischmann and Phalet, 2012). Looking beyond this common restriction, European countries are extending different histories of state–church relations to incorporate their Muslim citizens. For example, the Netherlands has publicly recognized and accommodated Muslim minorities by including Islam into a national history of religious pluralism. Contrarily, Islam has been denied formal recognition in Germany, where state support is restricted to historically established Christian churches. Also, France has been reluctant to accommodate Islam in accordance with a national tradition of secularism, or strict separation of church and state. These distinct institutional pathways entail different social realities for Muslim minorities across Europe. For example, only where Islam has been granted public recognition (e.g., in the Netherlands, not in Germany), are Muslim minorities able to combine sustained religious involvement with their social integration into mainstream society (Fleischmann and Phalet, 2012).

To conclude, migration histories and related patterns and policies of ethnic and religious diversity vary across Europe, yet they are clearly distinct from those in historical immigration countries such as Canada. In the European migration context, ethnic boundaries most often coincide with persistent social inequalities; and diversity policies usually fall short of multicultural accommodation.

Majority Perspectives on Ethnic Diversity: Attitudes and Intergroup Relations

Majority Attitudes and Intergroup Threat

In contrast to prevailing multiculturalism in historical immigration countries like Canada, representations of national culture and identity in European societies are more ethnically rooted and bounded, and hence less open to ethnic diversity (Verkuyten and Martinovic, 2012). In many European countries, issues of migration and ethnic diversity are highly contested in public debates and in the political arena; and inclusive integration policies are challenged by the rising tide of anti-immigrant parties and popular sentiments (Phalet and Kosic, 2006). From an intergroup-relations approach to prejudice, people will develop negative attitudes toward

those out-groups that are seen to threaten important in-group values or entitlements (Stephan and Stephan, 2000). Thus, when threat representations are induced by media images associating immigrants with crime or violence, or when threat is chronically salient, for instance, in the aftermath of terrorist attacks or in times of economic crisis or political turmoil, intergroup attitudes become more negative (Meeussen et al., 2012). Across Europe, many majority members see immigrant minorities as a threat to 'our' economic interests and cultural values (ESS, 2002). Such perceptions of threat reliably predict hostile attitudes toward minority members as well as restrictive acculturation expectations (Brown and Zagefka, 2011). Accordingly, most majority members demand that immigrants adopt the dominant culture and way of life; and they disapprove the desire of many immigrants to maintain their ethnic cultures and identities (ESS, 2002).

Particularly, public opinion surveys reveal a general trend toward more hostile majority attitudes toward Muslim values and ways of life (Voas and Fleischmann, 2012). Moreover, majority members tend to perceive Islamic and European values, and ways of life as mutually exclusive or incompatible (Chryssochoou and Lyons, 2011; Verkuyten and Martinovic, 2012). This is evident, for instance, from majority perceptions of Muslim family and political values as violating egalitarian gender role values and democratic rights and liberties in European societies. More generally, restrictive acculturation expectations among majority members are premised on an acculturation model that defines minority and majority cultures and identities as conflicting commitments (Van Acker and Vanbeselaere, 2012). For instance, Belgian majority members perceived the preference of Turkish immigrants to maintain their minority culture as incompatible with embracing the Belgian culture (Chryssochoou and Lyons, 2011). Perceived incompatibility suggests that Berry's 'integration' model of acculturation (Berry, 2001), which combines dual orientations toward majority and minority cultures and identities, may not always travel well to European migration contexts.

Media Representations and Contact Experiences

Feelings of threat and negative attitudes are not restricted to disadvantaged and typically most prejudiced segments of the majority population (ESS, 2002). Nor are they consensual or inherent in the dominant group position of majority members, as evident from ongoing public debates and deep political divisions over diversity issues within majority groups (Meeussen et al., 2012). Looking beyond classic prejudice research, therefore, social–psychological research looks for explanations of majority attitudes in the way intergroup relations with immigrant minorities are represented in society at large and experienced in daily contact situations.

First, restrictive majority attitudes have been related to prevailing media and political representations of immigrant minorities as threatening majority culture, welfare, and safety (Van Acker, 2012). Thus, content analysis of Flemish-Belgian newspapers, Internet forums, and party platforms revealed a widespread 'threat representation,' where minority members are seen to threaten majority interests and values. Threat representations associate immigrant minorities with negative stereotypes of terrorists or fortune seekers and thus, attribute responsibility for social problems to minority actors ('blaming the victim'). The findings suggest that, by diverting responsibility away from the majority group, threat representations in media and politics serve to legitimize restrictive diversity attitudes and policies. In contrast, a less frequent 'discrimination' representation sees majority members as discriminating or disrespecting immigrant minorities. The latter representation attributes responsibility for social problems to majority actors or policies. In an experimental follow-up study, Belgian participants were randomly assigned to reading realistic media messages either on 'intergroup threat' or on 'discrimination' (versus a control condition) and then reported their acculturation attitudes. Generally, restrictive acculturation expectations in the control condition were replicated or reinforced in the threat condition and they were significantly attenuated in the discrimination condition. Participants were most reluctant to support minority culture maintenance after reading a threatening media message, and most supportive after reading about discrimination.

Another example comes from a study about a real-life event, the 'Van Gogh murder' in the Netherlands. Van Gogh was a prominent Dutch film producer, who was assassinated by a Moroccan-Dutch Muslim allegedly due to his film criticizing the way women are treated in Islam. A study of intergroup threat in Dutch media following this incident (Meeussen et al., 2012) showed that the way intergroup events are framed in mass media can reinforce or attenuate negative majority attitudes. Specifically, media coverage of dissenting minority voices, e.g., condemning the violent act of a fellow Muslim as violating Islamic norms and values, effectively buffered the generalization of threat feelings to the (Muslim) minority group as a whole. To conclude, prevailing threat representations can be effectively challenged by exposing majority audiences to alternate perspectives or minority voices.

Finally, threat representations at the societal level have repercussions for daily experiences of intergroup contact with minority members. An extensive research tradition on intergroup contact reveals positive contact with minority members as a powerful tool to reduce prejudice (Pettigrew and Tropp, 2006). Against the background of less welcoming diversity climates and majority attitudes in Europe, however, the real-life contact experiences of majority members are often restricted and not always positive. More attention should be paid to the impediments of structural inequalities and legitimizing ideologies in real-life interactions between majority and minority group members. For instance, a diary study in ethnically mixed secondary schools in Belgium shows that pupils who endorse a threat representation of majority–minority relations, actually experience more threat and less positive effect in their daily interactions with minority members (Van Acker, 2012). This finding suggests that threat representations at the societal level are sustained by self-reinforcing cycles of threat through negative contact experiences. In contrast, endorsement of an alternative representation of discrimination predicted more positive effect and perspective taking during daily interactions.

Minority Perspectives on Ethnic Diversity: Acculturation and Adjustment

Minority Acculturation: Culture Maintenance and Religious Identity

In this last section, the authors turn to minority perspectives. Generally, restrictive majority attitudes impose pragmatic constraints on the acculturation options that are open to minority members (the viability question); and they affect the trade-off between psychological costs and rewards attached to bicultural integration (the adaptivity question). Berry's 'integration' type of acculturation attitudes refer to the preference to combine both minority and majority cultures and identities, in contrast with monocultural preferences, either for the minority culture ('separation') or for the majority culture ('assimilation'). Cross-cultural research with immigrant minorities shows that the second generation most often continues to attach high importance to the minority culture. In addition, they also report some measure of belonging to the majority culture, albeit levels of national identification among minorities are lower on average than among the host majority (Berry et al., 2006). While there is considerable variation in the self-relevance of the majority culture and identity, the psychological reality of most minority members and of the second generation in particular, is thus bicultural. More precisely, the majority culture becomes psychologically significant against the background of a continued and strong attachment to the minority culture (Verkuyten and Martinovic, 2012). This is best illustrated by a major cross-cultural study of the acculturation experiences of minority youth (Berry et al., 2006), which includes historical immigration countries as well as West, South, and Central European countries. The comparative findings confirmed that bicultural integration was indeed most preferred overall; and that integration predicted equally or more positive adjustment outcomes for minority youth relative to separation or assimilation.

Minority acculturation and adjustment vary considerably with the warmth of welcome in intergroup relations, however. To take into account different intergroup climates, recent research on acculturation and intergroup relations develops a multigroup perspective that combines majority and minority acculturation attitudes in particular intergroup settings. This research yields converging evidence of mutual influence between ('perceived') majority and minority acculturation attitudes; and relates diverging minority and majority attitudes (e.g., between majority Dutch preference for assimilation and minority Turkish preference for separation) to increased threat feelings and more negative intergroup attitudes (Brown and Zagefka, 2011). In European migration contexts, minority integration is often at odds with majority demands of assimilation. In these contexts, therefore, minority and majority cultures were more often experienced as conflicting; and separation was sometimes preferred over integration (for instance, by Turkish minority youth). Taken together, the evidence qualifies the psychological viability of integration, especially in more recent and less diverse European migration contexts.

One example of minority culture maintenance despite restrictive majority attitudes and discrimination is the importance of religion among second-generation Muslims in Europe. Sustained religiosity is well documented for the Turkish and Moroccan second generation in several European countries (Güngör et al., 2011). Religious continuity was related to the religious socialization of the second generation within close-knit immigrant families and communities. Immigrant parents purposefully and successfully instilled Islamic religious attachments, practices, and beliefs in their children. In parallel, coethnic peer networks further reinforced religiosity. Religious socialization in childhood predicted religiosity later in life through orientating children toward heritage culture maintenance. In line with an integration type of acculturation, religious socialization was unrelated to mainstream culture adoption.

Depending on different diversity climates in European societies, religiosity may also take on a reactive edge, however, opposing religious maintenance to mainstream culture adoption (Voas and Fleischmann, 2012). Cross-national comparisons provide evidence for more strict or reactive forms of religiosity in acculturation contexts that are antithetical to multiculturalism (for instance, in Germany (Fleischmann and Phalet, 2012)). Similarly, and in line with reactive religiosity, some evidence associates personal experiences of discrimination with increased religious identification and more strict forms of religious practice among second-generation Muslims. At the same time, there is also evidence of integration, combining sustained religiosity with majority culture contact and adoption. For instance, the religious attachment of second-generation Turkish-Belgian Muslims was compatible with positive attitudes toward adoption of the Belgian majority culture (Güngör et al., 2011). To conclude, the evidence on the psychological viability of strong religiosity in bicultural Muslims is mixed and likely to vary with the prevailing diversity climate.

Minority Adjustment: Bicultural Integration and School Performance

Turning to the adaptivity question, the adaptive value of minority acculturation attitudes, and of integration in particular, depends crucially on the acceptance of diversity by host majorities (Brown and Zagefka, 2011). To document the interplay of majority attitudes with minority acculturation and adjustment, the authors discuss in some more detail recent research on minority acculturation and school success. Schools are intergroup contexts that can make distinctive minority identities salient; and that attach more or less value to minority cultures and identities. When the school context explicitly or implicitly conveys the message that one's minority identity is valued and accepted, the school becomes an 'identity safe' learning environment for minority students. On the contrary, when the school disregards or devalues minority identities, this amounts to an 'identity threatening' environment. From the perspective of minority students, the school composition (e.g., ethnic segregation), the quality of intergroup contact (e.g., discrimination experiences), as well as salient negative stereotypes about the academic competence of minority groups are possible sources of identity threat (Baysu et al., 2013). In a field experiment in ethnically diverse Belgian schools, experimentally induced stereotype threat increased

test anxiety and decreased minority performance on a verbal analogies test, but only among participants who had experienced discrimination in school (Baysu, 2011). The interaction of chronic and situational forms of identity threat on minority performance suggests that early experiences of discrimination may have long-lasting consequences by making minority children vulnerable to stereotype threat in the classroom.

Integration often (although not always) predicts better psychological adjustment for minority members, including school success (Berry et al., 2006). In identity threatening contexts, however, when the majority rejects the double membership claims of minorities, integration may have less positive consequences for minority well-being and success. Accordingly, Turkish minority members who were high on integration were found to be more vulnerable in discriminatory school environments (Baysu et al., 2011). Thus, integrated Turkish students who reported more personal experiences of discrimination in school were more likely to leave school early and less likely to enter higher education than their assimilated or separated peers. In contrast, integrated Turkish pupils who had little or no experiences of discrimination had better chances of school success than their separated or assimilated peers. An experimental follow-up study similarly assessed the acculturation attitudes of Turkish and Moroccan minority members in Belgian schools (Baysu, 2011). Rather than using self-reported discrimination experiences, however, this study experimentally induced identity threat. Immediately preceding a verbal ability test, the experimental condition activated negative stereotypes of minority students as lacking in Dutch language mastery. Again, integrated participants showed worse performance, lower state self-esteem, and more negative feelings of frustration and anxiety under threat. In contrast, in the absence of threat, they were doing much better and they outperformed their peers with separation or assimilation attitudes. Finally, a study in British schools found longitudinal evidence of the psychological costs of integration in an achievement context (Brown et al., 2013). Asian minority children with an integration strategy of acculturation, while reporting higher levels of self-esteem and peer acceptance, also evidenced more emotional symptoms of social anxiety in school than children with either separation or assimilation strategies.

To conclude, the findings suggest that integration is a two-edged sword (see also Chryssochoou and Lyons, 2011; Simon et al., 2013; Wiley and Deaux, 2011), enabling sustained school engagement and better performance in the absence of identity threat, yet yielding most negative outcomes under identity threat. This is especially relevant for a better understanding of minority acculturation and adjustment in European migration contexts, which are generally less welcoming and less sympathetic to multiculturalism. In the words of a second-generation Turkish-Belgian youngster: "However hard we try, as long as Flemish society does not accept us and always, whatever we do or say, underlines that 'They are Turks, they are Muslims anyways', we cannot fully integrate. We will always be called, and defined as, Turk and Muslim. …Still, I live here. I work here. I have everything here. Turkey is my motherland. Belgium is my fatherland. I should be equally part of both."

Conclusion

This article reviewed selected research from both minority and majority perspectives on diversity. Minority and majority attitudes and experiences are situated against the background of a less welcoming diversity climate in today's Europe. Taken together, social–psychological findings suggest that ethnic diversity can be a divisive or a positive force; and that much depends on the way societies organize and represent intergroup relations between immigrants and hosts. In spite of persistent ethnic inequalities in most countries, diversity patterns vary widely across Europe. Similarly, diversity policies usually fall short of multicultural accommodation, yet they can be more sympathetic – or antithetical – to multiculturalism. The resulting diversity climate at the societal level shapes the diversity attitudes and experiences of both majority and minority members. Thus, common threat representations of immigrant minorities in media and politics predicted more restrictive acculturation attitudes and less positive daily contact experiences in majority members, suggesting self-reinforcing cycles of threat engendering more threat. Importantly, alternate views and minority voices effectively can break this cycle of threat, for instance, through shifting group perspectives or responsibility attributions. Similarly, on the minority side, European research findings qualify the psychological viability and adaptive value of bicultural integration, or the combination of minority and majority cultures and identities, in less welcoming environments. For instance, evidence of so-called reactive religiosity suggests that Muslims who experience personal discrimination perceive their religious identity as incompatible with the majority culture. Not only the psychological viability but also the adaptive consequences of integration depend crucially on majority attitudes toward diversity. For instance, bicultural integration made minority students most successful in so-called identity-safe school environments, where diversity is accepted and valued. In contrast, in an identity-threatening environment or situation, for instance, in the presence of stereotype threat or when experiencing discrimination, students with an integration strategy of acculturation were least successful. Taken together, these new social–psychological findings lay out an emerging European research agenda for the social psychology of migration and ethnic diversity. They combine parallel and hitherto largely separate research streams on majority prejudice and minority acculturation. To articulate an integrative intergroup-relations perspective on ethnic diversity, the studies the authors reviewed develop a multigroup and multilevel approach of minority and majority experiences in different societal contexts. To this end, they cover the full range of cross-nationally comparative, longitudinal, and experimental research strategies in social psychology. While diversity issues are commonly associated with images of the threatening immigrant or Muslim, social psychology is well equipped to articulate different experiences and representations of diversity as a challenge for Europe.

Ethnicity: Anthropological Aspects

Richard Jenkins, University of Sheffield, Sheffield, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article opens with a brief discussion of the historical centrality to anthropology of a particular model of collective identity – the small-scale, territorially defined, corporate group – and a related assumption of bounded cultural differentiation. Reflecting a gradual move away from perspectives rooted in evolutionism and colonialism, the anthropological model of collectivity has changed, from the tribe to the ethnic group or community. Ethnicity in one sense or another remains the dominant current framework, and its key themes are membership and boundary. There are two major anthropological positions: the transactionalist or situationalist, following Barth (with an intellectual pedigree stretching back to Weber), and the primordialist, usually attributed to Geertz (and deriving from the European Romantic tradition). The disagreement between the two points of view rests at least in part on a misreading of both Barth and Geertz. It is possible to identify a basic anthropological model of ethnicity that accommodates understandings of ethnicity as both negotiable and situational, and potentially deeply rooted and powerful in its consequences.

The ancient Greek word *ethnos*, referring to human collectivities living and acting together, is typically translated today as 'people' or 'nation.' Over the last 100 or more years, the concepts of ethnicity and ethnic group that are derived from it have passed into everyday discourse. They are central to the politics of group differentiation and advantage in the culturally diverse democracies of Europe and North America. With notions of 'race' in disrepute since 1945, ethnicity became a rallying cry in the bloody reordering of the post–Cold War world: 'ethnic cleansing' stands shoulder to shoulder with earlier euphemisms such as 'racial hygiene' and 'the final solution.' In the markets of the affluent West and North, to call a commodity 'ethnic' is to imply the value of 'authenticity.' In the social sciences, ethnicity – including related topics such as racism, nationalism, and diversity – is a long-established speciality.

Corporate Groups and Cultural Differences

One of anthropology's earliest ambitions as a comparative scientific enterprise was to explain and understand human diversity. This aspiration remains central to the social and cultural anthropological imagination – and to the limited, but significant, unity of purpose that divergent national and intellectual anthropological traditions have succeeded in maintaining – ever since. The different approaches to this quest that have characterized the discipline's twentieth-century history have generally been rooted in two interrelated anthropological axioms. On the one hand, there is an understanding of human social life as based in membership in definite, bounded *corporate groups*. On the other, the basic unity of humankind is understood as crisscrossed by patterns of *cultural differentiation*.

These fundamental concepts emphasize similarity (corporate groups) and difference (cultural differentiation), the two basic dimensions of all processes of social identification. In groups we are both together (as us) and apart (from them). Although the two notions, and their implication in each other, remain constant, how they are defined, and the relationship between them, has changed since the nineteenth century. There has been a gradual shift from documenting the social structure and customs of 'tribes' to attempting to understand the complex dynamics of 'ethnic groups.'

During the colonial and immediately postcolonial eras, anthropology's theoretical preoccupation with corporate groups was manifest in the assumption that 'primitive peoples' were characteristically organized into tribal groups. In one move, the concept of 'the tribe' distanced tribal society from civilized society, in both everyday and analytical discourse, and provided the anthropologist with a theoretical model of the nature of 'uncivilized' social organization that could organize ethnographic data and function as a framework for cross-cultural comparison. At the same time as the difference between 'them' and 'us' was established, the basic similarity between different sorts of 'them' was proclaimed. This 'tribe-group' model was not, however, an explicit analytical framework; it was, rather, implicit in most ethnographic studies, neither examined nor questioned.

The Anthropology of Ethnicity

One of the earliest anthropologists to doubt the usefulness of the notion of the tribe was Edmund Leach, who argued, in his study of highland Burma (1954), that tribes, as discrete bounded entities, were essentially models developed by outsiders, for their own purposes, not locally meaningful principles of everyday social organization. Locals might talk about themselves *as if* there were clear-cut collective identities and entities, but everyday interaction and organization revealed a more complex pattern of overlap, variation, and fluidity.

By the 1960s, the notion of 'the tribe' was gradually being replaced in British social anthropology by the perhaps less colonial-sounding 'ethnic group.' However, the underlying assumptions about corporate groups and cultural difference had probably not changed much. Within American anthropology, the increasing use of an ethnicity model, over the same

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12062-8

period, can also be understood as part of a long-term, incremental shift in the discipline's axiomatic meta-theoretical model of difference: from 'race,' to 'culture,' to 'ethnicity' (Wolf, 1994).

Ethnic Groups and Boundaries

The paradigm shift toward a social constructionist model of ethnic groups followed the publication of the Norwegian symposium edited by Barth, *Ethnic Groups and Boundaries* (1969). The subtitle of this collection of essays – "The Social Organization of Culture Difference" – tells us a great deal about both anthropological understandings of ethnicity (cultural differentiation) and Barth's take on it (as social organization). In the introduction, he argued against the presumption that the social world was made up of 'distinct named groups.' Ethnicity, the boundaries of ethnic groups, and indeed their ontological status as collectivities, could not be accepted uncritically as fixed aspects of the social reality in question. Instead, Barth insisted that ethnic identity – and its production and reproduction in routine social interaction – must be treated as essentially problematic features of social life, as emergent properties of everyday interaction. The ethnographer must examine the practices and processes whereby ethnicity and ethnic boundaries are socially constructed.

Barth and his colleagues shifted the anthropological emphasis from the static evocation of tribal identity as a feature of social structure to a recognition of ethnic identity as a dynamic aspect of social organization: ethnic identification is something that people can and do manipulate, depending on the needs and possibilities of the context. People are not 'at the mercy' of their ethnicity, nor do they do things simply because they are ethnically 'X' or 'Y.' Ethnicity is not an imperative. In acknowledging this, *Ethnic Groups and Boundaries* marked a shift from an interest in the 'uncivilized' peoples of the colonies and ex-colonies to a more equitable concern with the complex heterogeneity of all societies.

Barth's emergent alternative framework had several key features. First, the analysis of ethnicity starts from the definition of the situation held by social actors. Second, the focus of attention then becomes how ethnic boundaries are maintained or changed in the structured interaction between 'us' and 'them' that takes place across boundaries. Third, the ethnicity of actors is not necessarily fixed; it is situationally defined. Fourth, ethnic identity depends on ascription, by members of the ethnic group in question and by outsiders with whom they interact. Fifth, ethnicity is not a matter of 'real' cultural differentiation; differences are in the eye of the beholder; the 'cultural stuff' that had been hitherto believed to determine group identification is somewhat irrelevant. Finally, ecological issues are influential in producing and reproducing ethnic identity: economic competition for scarce resources plays an important role in the generation of ethnicity.

Ethnicity as Socially Constructed

Barth's social constructivist model of ethnicity can be traced back to the ideas of sociologists such as Max Weber, Everett Hughes, and Erving Goffman. Although *Ethnic Groups and Boundaries* was the model's most systematic, extended, and influential statement, similar arguments can also be found in the work of contemporary North American anthropologists such as Moerman (1965) and Cohen (1969). It has dominated discussions of ethnicity within European and North American anthropology ever since.

Handelman's development of this paradigm (1977) acknowledged the importance of boundaries, and the situational negotiability of ethnic membership. However, he argued that Barth overemphasized the centrality of social interaction in establishing boundaries, at the expense of acknowledging the role of culture. For Handelman, the cultural content of ethnicity is an important aspect of its social organization; a dichotomy between the cultural and the social is misleading. He argued further that ethnicity is incorporated – made socially significant – in differing degrees of intensity and territoriality, on which depends its salience in individual experience. Moving from 'the casual to the corporate,' Handelman distinguished the *ethnic set*, the *ethnic category*, the *ethnic network*, the *ethnic association*, and the *ethnic community*. Ethnicity can, for example, organize everyday life without ethnic *groups* featuring locally as meaningful social forms, an insight that Brubaker has since developed (2004).

This anthropological model of ethnicity has become a normal science paradigm to the degree that it is somewhat taken for granted. It has many virtues. In stressing flexible social process and the practices of actors, it encouraged a move away from the various strands of determinism of the 1970s and early 1980s. The emphasis upon social construction discourages the intrusion of biological conceptions of ethnicity or race into social analysis. Finally, the importance that is attached to the views and self-perceptions of social actors themselves undermines the taken-for-granted ethnocentrism of much social science. These are important gains, and in all of these respects the approach anticipated some of the valuable aspects of postmodernism and poststructuralism.

However, the approach has suffered at the hands of some of those who have most wholeheartedly embraced it. In stressing concepts such as 'group,' 'category,' and 'boundary,' and processes of 'maintenance,' Barth – despite his intentions to the contrary – contributed to the further reification of the ethnic group as an enduring corporate entity. In particular, the spatial and physical overtones of the notion of the 'boundary' allow the superficial or the careless to celebrate the situational flexibility of ethnicity without taking on board the more difficult questions about the nature of collective social forms in which Barth is interested. In their enthusiasm for processes of boundary maintenance – negotiation and strategizing – many of those whose analyses owe much, if not everything, to Barth have taken for granted what he did not, that is, the 'group' that is the object of the research.

Three other, related, criticisms are worth mentioning. First, although the locations where Leach, Barth, and others did their fieldwork – South-East Asia and the Middle East, for example – do allow for flexibility and a degree of choice with respect to identification, the same is not true everywhere. In many other contexts, such as Northern Ireland or Kosovo, there may be much less room for maneuver. Second, many anthropologists, in their celebration of the positivities of everyday life, still appear reluctant to accord full significance to power imbalances; this, however, is changing (Gledhill, 2000). The third

criticism concerns the relative lack of theoretical attention that has been given to the relationships between ethnicity, on the one hand, and other principles of social identification, particularly class and stratification, on the other.

None of these problems, however, are inescapable theoretical weaknesses of the general anthropological approach. Recently, a solution to some of them has been put forward in the application of the distinction between *groups* and *categories* to the study of inter-ethnic relations (Jenkins, 2008). It is important to distinguish between two analytically distinct processes of ascription: *group identification* and *social categorization*. The first occurs inside the ethnic boundary (group members identify themselves), the second outside and across it (a collectivity and its members are categorized by nonmembers). Social categorization, in particular, is intimately bound up with power relations. It reflects the capacity of one group successfully to impose its categories of ascription upon another set of people, and the resources that the categorized collectivity can draw upon to resist that imposition. Acknowledging the significance of this distinction places relationships of domination and subordination on the theoretical center-stage.

Ethnicity as Personally Meaningful

If ethnic identity is a flexible matter, dependent on situation, it is legitimate to ask what it *really* means to the individuals concerned. This question has generated discussion about the nature of ethnic identity, and is a perennial textbook topic. Is ethnicity a fundamental, *primordial* aspect of human existence and self-consciousness, unchanging and unchangeable in the demands it makes upon individuals and the bonds it creates between the individual and the group? In other words, is ethnicity an aspect of human nature? Or is it, to whatever extent, defined *situationally*, strategically or tactically manipulable, and capable of change at both the individual and collective levels? Is it, indeed, wholly socially constructed, as the post-Barth conventional wisdom might suggest?

This debate takes its place alongside philosophical controversies about human nature, the human condition, and the capacity of humans to intervene in their own lives, to determine or to be determined. But the 'primordial model' also has other historical roots, in the Romantic reaction to Enlightenment rationalism. Finding some of its more respectable voices in Herder and Hegel, primordialism naturalizes ethnic groups and justifies chauvinistic ethnic sentiments, providing an intellectual charter for murderous ethnic chauvinism, nationalism, and genocide.

Academically speaking, primordialism can be identified in debates about the modernity and nature of nationalism (e.g., Smith, 1994). The anthropologist who is most often identified with a primordial model of ethnicity is Geertz (1973: pp. 255–310). Writing originally in 1963, Geertz was concerned to understand the obstacle that 'primordial attachments' – such as tribalism, parochialism, or communalism – posed to the development of the modern political sentiment of citizenship in emergent postcolonial 'new states.' This was an important recognition that, whatever else it is about, ethnicity is also about affect, and the sometime power of culture to move people.

So, on the one hand, we have negotiable identities, while on the other, there are primordial attachments. The apparent conflict between the 'primordialist' and 'situationalist' perspectives is, however, not as clear-cut as it seems. It is hard to resist the conclusion that the debate has generated more heat than light. The protagonists are certainly usually misrepresented, sometimes to a remarkable degree.

To look at what Geertz actually said, he explicitly recognized the role of culture in defining the primordial 'givens,' and that primordial attachments are historically and situationally variable in their power to move people. He is also clear that what matters is that ties of blood, language, and culture are *seen* by actors to be ineffable and obligatory; that they are *seen* as natural. He is concerned with the terms in which attachments are understood and mobilized locally; with what people *believe*. Finally, Geertz further argues that these putative 'primordial attachments,' far from being necessarily ancient, may actually be stimulated and quickened by the political modernization of nation-building.

Barth, for his part, has never neglected the power and stability of ethnic identifications. As much concerned with the persistence of ethnic boundaries as with their flux, what he said was that under certain, not uncommon, circumstances ethnic change *can* happen, not that it *must*. Furthermore, his point of view is often presented fossilized in its 1969 incarnation. Since then he has explored the importance of ongoing, and historically relatively stable, 'streams of tradition' or 'universes of discourse' within the constraints of which ethnic identities are produced and reproduced in practice. Most recently, he has acknowledged the need to add micro and macro levels of analysis to the intermediate level upon which his original arguments concentrated. This means looking at what ethnicity means for individuals.

There are other reasons for becoming impatient with this debate. In the evocative words of one teaching text, it offers a contrast between 'ethnicity in the heart' and 'ethnicity in the head' (Banks, 1996: pp. 185–187). This alerts us to the need to acknowledge affect and emotion in our considerations of ethnicity. But there is no necessary contradiction between instrumental manipulation, on the one hand, and sentiment on the other. They may, in fact, go hand in hand. They may also, of course, conflict; but so may different sentiments or opposing instrumental goals.

There is, however, good reason to reject totally any strongly primordialist view. Too much ethnographic evidence exists of the fluidity and flux of ethnic identification, and of the differing degrees to which ethnicity organizes social life in different settings, for any other position to be sensible. However, we cannot deny the longevity and stubbornness, under particular circumstances, of ethnic attachments. But to acknowledge this point does not necessitate either embracing a primordial model or abandoning the idea of social construction. It is not stretching the point to regard ethnic differentiation – the social construction of 'us' and 'them,' marked in cultural terms – as a ubiquitous feature of human sociability, and hence of all human societies. Arguments about whether or not ethnicity is 'situational' *or* 'primordial' confuse the ubiquity of a social phenomenon such as ethnicity with implacable presocial powers of causation. To suggest that ethnicity is ever-present, as one of the 'givens' of human social life, is not to endorse primordialism.

Within anthropology, the primordial intellectual position is unconvincing largely because it is something of a straw man. Debates about 'instrumentalism' and 'primordialism' exaggerate the differences between, for example, Geertz and Barth, and do neither justice. More broadly, it is tempting to suggest that the notion of the 'primordial' should be banished from the social science lexicon altogether. On the other hand, however, it would be irresponsible to forget the debate altogether. Crude primordialism is essentially a common-sense view, with enormous power in the world. It still occasionally makes an academic showing in the guise of sociobiology – now calling itself 'evolutionary psychology' – and discussions about territoriality. These views cannot be simply ignored, and an anthropological perspective, rooted in social constructionist assumptions, has much to offer as a critique of the naturalization of chauvinism and ethnic conflict.

A Basic Anthropological Model of Ethnicity

Despite the criticisms and debates summarized here – and in unacknowledged harmony with post-1980s discourses about 'difference,' globalization, trans-nationality, and so on – a 'basic anthropological model of ethnicity' remains in place as disciplinary conventional wisdom. In its foundational emphasis upon social construction, its recognition of the fluidity as well as the solidity of identity, and its refusal to biologize or naturalize what are sociocultural phenomena, it remains the cornerstone of *any* anthropological approach to the topic. It can be summarized thus:

- Ethnicity is about cultural differentiation (bearing in mind that similarity and difference are inextricably connected).
- Although ethnicity is centrally concerned with culture – shared universes of meaning – it is also rooted in, and to a considerable extent the outcome of, social interaction.
- Ethnicity is no more fixed or unchanging than the culture of which it is a component or the social situations in which it is produced and reproduced.
- Ethnicity as a social identity is collective and individual, externalized in social interaction and internalized in personal self-identification.

However, that there is a *relatively* consensual model, combined with the anthropological enthusiasm for detailed ethnography rather than systematic theory, may lead to some things being taken for granted. In particular, there is a perpetual need to struggle against the tendency to reify culture and ethnicity. Although we talk about them in these terms, neither culture nor ethnicity is 'something' that people 'have' or to which they 'belong.' They are, rather, complex repertoires that people experience, use, learn, and 'do' in their daily lives, within which they construct an ongoing sense of themselves and an understanding of their fellows.

The reification of ethnicity may also lead to its being seen as typically – or even only – an attribute of the Other. We need to remind ourselves all the time that each of *us* participates in an ethnicity – perhaps more than one – just like *them*, just like the Other or 'the ethnic minorities.' *National* identity may, however, be easier to recognize in ourselves than ethnicity. Nationalism and the construction of national identity are explicit projects of the state (and, if nothing else, we have passports). In the 'modern world,' the contours and contents of national identity, and the contexts of its uses and justifications, may be more visible than ethnicity. It is therefore no surprise that the anthropology of nationalism is a growth area (Eriksen, 2010), or that the developing field of 'border studies' – focusing inter alia on the processual and cultural character of national boundaries – owes much to the anthropological model of ethnicity (Wilson and Donnan, 2012).

Although anthropologists may not have to remind themselves that national identity, as a variation on the theme of ethnicity, is socially constructed, there is a need to keep this idea firmly in the public eye. The timeliness of Wolf's warning (1994) that 'race,' 'culture,' and 'people' are 'perilous ideas,' makes the social constructionist, anthropological model of ethnicity as relevant now as it was in the 1960s. Anthropology's comparative global reach and ethnographic research approach, its emphasis upon culture and social construction, and its capacity to see individual trees as well as the collective wood, relativizes notions about ethnicity and undermines the naturalization of ethnic or national identity. That remains a vital contribution to our understanding of the modern world.

Abstract

In 1987, the Canadian Association of Schools of Social Work adopted policies and accreditation standards that reflect the profession's commitment to address issues of race, ethnicity, and cultural diversity in its programs and curricula. Task force recommendations to emphasize antiracism in schools of social work were contested and resisted. Since then, various shifts in perspectives have emerged and adopted in social work to varying degrees. Despite efforts to advance antiracism, and more specifically anti-Black racism and anticolonialism in social work education, anti-oppression has been more palatable to mainstream social workers. To advance the profession, these perspectives must be understood and addressed.

Introduction

Canada as a white settler society has a strong aversion to speaking about racism. This is despite the existence of the *Canadian Multiculturalism Act* of 1988 (Haque, 2012), which aims to recognize cultural and racial diversity and acknowledge the freedom of all Canadians to preserve, enhance, and share their cultural heritage. The Act was purposed to promote full and equitable participation of individuals and communities in building the Canadian nation state (Henry and Tator, 2010; Thobani, 2009). The Act influenced Canadian discourses of race and racism (St. Denis, 2011). However, the extent of its influence is not yet fully realized because there remains a deeply engrained aversion to speaking about racism in Canadian institutions (Henry and Tator, 2010; Simpson et al., 2011; St. Denis, 2011).

The profession of social work is not immune to avoiding discussions about racism in Canada. Most schools of social work in Canada do not address issues of race and ethnicity very well, and only few require mandatory courses on antiracism in their curricula (Henry and Tator, 2010). Henry and Tator (2010) contend that most schools of social work do not prepare students well to work with racialized and Aboriginal populations. Lena Dominelli has called for a social work praxis that addresses racism at the individual, systemic, and structural level (Dominelli, 1988). Yet, many schools of social work continue to embrace social order perspectives such as systems and ecological theories that seek to understand individuals in relation to their environments (Mullaly, 1997). These approaches do not address systemic and structural forms of oppressions including racism and its intersecting correlates (Carniol, 2010). Rather, they emphasize assimilationist perspectives, which merely reify whiteness (Razack, 2002).

In the late 1970s and 1980s, social work scholars such as Maurice Moreau, Bob Mullaly, and Ben Carniol advanced structural social work, which seeks to 'redefine problems in their material and collective contexts,' and transform intersecting oppressions such as racism, classism, ableism, sexism, and gender inequality (Moreau, 1979: p. 17). Groundbreaking publications including Ben Carniol's *Case Critical: The Dilemma of Social Work in Canada* (1987) and Bob Mullaly's *Structural Social Work* (1997) hold that addressing individual problems and aspects of social differences are inseparable from larger systemic and structural factors. Thus structural social work responds to the limitations of social order perspectives such as systems and ecological theories (Mullaly, 1997). More recently in Canada, anti-oppression perspectives in social work have grown in popularity.

This article argues that anti-oppression discourses often silence antiracism. We assert that a commitment to preparing social work students to effectively meet the needs of ethnic, cultural, racialized, and Indigenous populations require deliberate attention to critical race feminism and anticolonialism frameworks that challenge the liberalism of multiculturalism and intentionally address systemic and structural barriers affecting these populations. Toward this end, we assert that schools of social work must address issues of colonialism and racism in their programs and curricula, including anti-Black racism.

A Historical Perspective of Race and Social Work Education

At the Canadian Association of Schools of Social Work (CASSW) general assembly in 1987, members voted in favor of adopting policies and accreditation standards that "reflect social work education's commitment to prepare students to work effectively with diverse ethnic, cultural, and racial populations" (CASSW, 1991: p. 3). Subsequently the CASSW Board of Directors unanimously passed a motion to refer the matter to the Educational Policy Committee for advancement and integration. Hence, the Task Force on Multicultural and Multiracial Issues in Social Work Education was launched. By May 1991, the task force membership was established and their actions materialized in the publication of *Social Work Education at the Crossroad: The Challenge of Diversity*. Based on interviews with students, faculty, field, and community representatives, this document heralded the need for greater emphasis on antiracism in schools of social work. Its recommendations covered areas of organizational structure and policies, content, students, faculty and instructors, field work, and community. In 1992, according to the CASSW, all schools of social work were to revise their education policies to reflect the changes in accreditation standards.

Since the 1991 CASSW document, Canadian schools of social work have undergone various changes in perspectives in response to cultural and racial diversity. However, many schools responded with resistance (Henry and Tator, 2010). Some of the resistance to antiracism took the form of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28107-5

accusations that its proponents were creating a hierarchy of oppressions (Barnoff and Moffatt, 2007; McLaughlin, 2005), which placed racism as the most salient or pressing oppression. Given the severe discomfort and volatility that was generated by discussions of antiracism in social work, it was not unsurprising that a shift emerged in Canada from antiracism to anti-oppression (McLaughlin, 2005; Pon et al., 2011). To understand this dynamics, we next examine efforts to advance antiracism in Canadian social work.

Efforts to Advance Antiracism in Social Work

In the 1990s, from African Canadian grassroots activism of teachers, community leaders, and academics, antiracism education emerged in Canada (Wood, 2000). Antiracism education would influence disciplines such as social work. Antiracism education challenged the liberalism of multiculturalism that emphasizes song, food, and festivals, while never having to name and examine whiteness (Razack, 2002). Antiracism uses race as the primary lens through which to understand and respond to intersecting and interlocking systems of oppressions such as racism, sexism, classism, heterosexism, and ableism (Dei, 2008). Using race as the point of entry is an explicit political stance to counter the pervasive denial of systemic and structural racism in Canada (Dei, 2008). Centering race also challenges "…benign conversations about culture and identity" and the management of diversity, which reproduces whiteness (Jeffery, 2005: p. 418).

The need for antiracism in social work is particularly pressing given Thobani's (2009) assertion that the rise of the postwar Keynesian welfare state in Canada was founded on principles of white supremacy that functioned to exalt white Canadian nationals as benevolent, kind, and caring, while simultaneously constructing racialized and Aboriginal people in Canada as constituting threats to the nation. Constructed as threats to nationalism, racialized immigrant and Aboriginal populations were deemed to be in need of surveillance and containment by social services workers (Thobani, 2009). A sustained consequence of this is the exclusion of racialized and Aboriginal people from equal and equitable access to social benefits. This inequity concerns social work, since its mission is to prioritize social justice especially for marginalized and vulnerable populations.

Integrating antiracism into social work education helps to prepare social work students to be change agents in practice. This is vital because current practice reflects an exclusion of racialized immigrants and Aboriginal people from employment in social services and as professors of social work. Henry and Tator (2010) noted that it is only in the 1990s that mainstream human services agencies in Canada began hiring from ethno-racial minority communities. For example, 94% of all child welfare workers in Canada are White (Fallon et al., 2003). Besides, racialized social workers face barriers such as lack of promotion opportunities, nonrecognition of foreign credentials, and devaluation of their knowledge and skills (Clarke, 2010, 2012; Gosine and Pon, 2010; Henry and Tator, 2010). Of equal concern is the exclusion of Aboriginal and racialized people from tenure stream positions in schools of social work in Canada (CASSW, 1991). These exclusions of individuals have led racialized immigrant communities in Canada to form their own social services organizations for the sake of survival (Thomas, 2006).

Organizations such as the Association of Black Social Workers (Thomas and Hamilton-Hinch, 2006), Black Action Defense Committee (Williams, 2005), and Urban Alliance on Race Relations (Urban Alliance on Race Relations, 2002) influenced the societal context of antiracism and challenged systemic racism in Canadian institutions. Despite their actions in challenging racial injustice, there is still resistance to antiracism discourse and a reliance on multicultural discourse in social work education and practice. However, as Lee and Bhuyan (2013) argue, "multicultural discourse in social work relies on a deficit model of culture, which according to social work historian Yoosun Park (2005), constructs culture as difference that must be managed" (p. 103). Further, multicultural social work promotes the discourse of cultural competency, which silences race and racism, depoliticizes culture as neutral and devoid of power relations, and fails to analyze the role of whiteness in social work (Pon, 2009).

The Silencing of Antiracism by Anti-Oppression Perspectives

In light of the criticisms leveled against antiracism, there has been a shift away from this perspective toward anti-oppression in social work. In the new millennium anti-oppression has emerged as a widely accepted approach to social work in Canada (Mullaly, 2002; Baines, 2010). McLaughlin (2005) asserts that proponents of antiracism such as Lena Dominelli (1988, 2002) shifted from antiracism to anti-oppression to avoid the contestation and appearance of a hierarchy of oppressions or ranking of oppressions (McLaughlin, 2005). Anti-oppression, unlike antiracism, does not use race as the point of entry or lens through which to view interlocking systems of oppression. Rather it purports to view all oppressions simultaneously and equally.

Anti-oppression aims to eradicate all forms of oppression. It is defined as "a form of social work practice which addresses social divisions and structural inequalities in the social work that is done with clients (users) or workers" (Dominelli, 2002: p. 36). Anti-oppression acknowledges worker power and expert knowledge and requires critical self-reflection to ensure an egalitarian client-centered practice (Healy, 2005). It is eclectic in its borrowing of critical perspectives including antiracism, feminism, Marxism, structuralism, postmodernism, and post-structuralism.

Several scholars have raised concern that anti-oppression discourse avoids debates about racism, while still seeming to be progressive (Pon et al., 2011; Razack, 2002; Williams, 1999). Others like Healy (2005), Briskman (2007) and Walter, Taylor and Habibis (2011) argue that the "focus on multiple forms of oppression dilutes and dissipates the significance of race in everyday and institutional interactions" Walter, Taylor and Habibis (2011, p. 12). For example, in a document entitled *Anti-Oppression Framework for Child Welfare in Ontario* (Wong and Yee, 2010), which is endorsed by all of Ontario's child welfare agencies, the word racism occurs only once in the body of the text, the word 'black'

appears only once, and colonialism, is never mentioned. This example calls attention to the way in which anti-oppression discourse silences and can easily avoid issues of racism and colonialism, while purporting to be responsive to diversity.

Toward a Critical Race Theory and Anticolonialism

Emergent calls to address anti-oppression limitations have pointed to critical race theory (Razack and Jeffery, 2002), critical race feminism (Clarke, 2012; Pon et al., 2011; Razack et al., 2010), anticolonialism (Pon et al., 2011; Sinclair et al., 2009), and decolonization (Baskin, 2010; Lavallée, 2007; Lawrence and Dua, 2005), especially as these theories address the fundamental stakes of white supremacy, imperialism, racism, settler colonialism, and interlocking oppressions. The extant literature on the ongoing colonialism and racism experienced by Aboriginal and racialized peoples in Canada is extensive (Baskin, 2010; Clarke et al., 2012; Dei, 2008; James, 1996; Lawrence and Dua, 2005). Despite this scholarship, there is relatively little discussion of racism and colonization in social work education. To address this gap, three Aboriginal professors Raven Sinclair et al. (2009) recently published a book titled *Wicihitowin: Aboriginal Approaches to Social Work*, which is a required reading for upper level students in the social work program at Ryerson University. The text provides social work students with knowledge of Indigenous worldviews, research and practice, the history of colonization, and processes of decolonization in Canada. While Indigenous content is incorporated into the social work curricula at Ryerson and such core courses are offered to students, these remain on the margin in many social work programs in Canada.

On the other hand, some schools have developed specific Indigenous programs that are grounded in Indigenous epistemologies (Sinclair et al., 2009). Although these programs are accountable to the Indigenous community and have Elders physically present in classrooms, they operate within the constraints of the CASSW, with national standards that marginalize Aboriginal ways of knowing (Bruyere, 2007). This problem is compounded by the relatively few Aboriginal (2.1%) and racialized (17%) faculty in the academy, which limits scholarship, research, and teaching (Canadian Association of University Teachers, 2010). Social work's attempt to bring *other ways of knowing* into its curricula is critical in order to "…challenge Eurocentric discourses" and "…subvert dominant thinking that re-inscribes colonial and colonizing relations" (Dei and Kempf, 2006: p. 3). Calls to address the limitations of antiracism and anti-oppression must also address the de-linking of antiracism and anti-colonialism in much of social work education, which helps to fuel discursive and political tensions between migrants, settlers, racialized, and Aboriginal peoples in Canada (Lawrence and Dua, 2005). Antiracism theory has been criticized for excluding an Indigenous perspective, and not reflecting on Indigeneity and ongoing colonialism in the settler society (Lawrence and Dua, 2005). As Lawrence and Dua (2005) contend, much of "Aboriginal activism against settler domination takes place without people of color as allies" (p. 120). As a profession, social work has not been able to effectively advance Indigenous decolonization or address racism and other forms of oppression, including the marginalization of Blacks. Thus, there is a need for social work education to focus on anti-Black racism.

Where to From Here? Anti-Black Racism in Social Work Education and Practice

The social work profession has been slow to address racism, colonialism, and white supremacy in Canada. Antiracism has helped to advance critical perspectives for understanding racism in Canada and the impact on racialized people (Dei, 2008; Henry and Tator, 2010; James, 2003). However, the antiracism movements to combat racism against Blacks in many Canadian institutions have been challenging. This has led to calls for the development of a framework that critically examines the specificities of the Black community with institutional racism, as evidenced by their overrepresentation in the criminal justice system and child welfare system; racial profiling in policing; disproportionate and extreme poverty; high levels of unemployment; and restricted access to housing and health care (African Canadian Legal Clinic, 2012). Social work's response to anti-Black racism has been minimal.

The term anti-Black racism was coined in the 1990s by Black leaders, grassroots activists, community members, and academics to reflect a particular type of racism that is directed at members of the Black community in Toronto and their resistance to this discrimination (Benjamin, 2003). Anti-Black racism began with a focus on racism in the criminal justice system, following a series of police shootings of Black men in Toronto and elsewhere in Canada, and the lack of restitution for these killings (Benjamin, 2003). The concept of anti-Black racism emerged out of internal political and ideological struggles and the external and systemic conditions of racism in Canadian society. It has drawn upon anticolonial, anti-imperialist, Marxist, Socialist, Feminist, Black Nationalist, and other political ideologies and stances, to understand and address the experiences of Black people (or African Canadians (Benjamin, 2003; Warner, 2006). As such, anti-Black racism constitutes dialectic between racism directed at Blacks and their resistance to this discrimination.

The concept of anti-Black racism, however, did not gain much traction until the Provincial government under the New Democratic Party (NDP) hired Stephen Lewis to conduct an investigation into what mainstream media termed the Yonge Street "riot" of 1992. This uprising occurred when members of Toronto's Black community and other social justice activists took to the street to resist police violence and harassment, and the killings of young Black men and women in Toronto and Halifax, and the Rodney King beating by White police officers in the United States (Benjamin, 2003; Warner, 2006). The Black Action Defense Committee (BADC) of Toronto, a grassroots organization that was formed in 1988 after the shooting of Lester Donaldson, led a coalition of Black community groups in a community-wide struggle against the shootings (Benjamin, 2002). Lewis met with members of the Black community and named anti-Black racism as a particular and severe experience of racism by African Canadians, particularly youth. Lewis' use of the term anti-Black racism validated the work of Black

community members who had been naming and resisting this form of discrimination for decades.

Anti-Black racism borrows from Gayatri Spivak's (1990) notion of strategic essentialism. This concept is a political and social act of uniting under a common identity such as Black in order to take effective action against social oppressions (Benjamin, 2003). Some argue that anti-Black racism affords Blacks 'special treatment' and supports a hierarchy of oppression (i.e., racism toward Black is worse than racism toward other racialized and oppressed groups). This argument misses two salient points. First, anti-Black racism recognizes that there are different forms of racism directed toward different groups and populations in Canadian society (e.g., slavery against Blacks; cultural genocide of Aboriginal peoples through the 1876 Indian Act; residential school system and their historic struggles against assimilation and for sovereignty; the internment of Japanese Canadians during the Second World War; and the indenture of Chinese settlers) (Henry and Tator, 2010). These specific experiences, struggles, and consequences demand differing ways to address the particularities of each group. This means attention is given to the specific struggles of Blacks. Secondly, anti-Black racism stands in solidarity with groups and communities struggling against their specific form of racism and other oppressions. Today, there is little usage of the concept or knowledge of anti-Black racism in social work.

The dialectic of anti-Black racism has much to offer social service agencies and the profession of social work, particularly insights into community organizing. Three key principles for community organizing have been advanced by BADC. The first principle is that the learning of past Black struggles is important to addressing systemic racism presently. Such learnings can come from Pan-Africanism, Black Radicalism, antiracism, Black cultural nationalist organizing, anti-imperialism, anticolonialism, postcolonial Black feminism, Black Queer, and other Black struggles (Benjamin, 2003). The political struggles of anti-Black racism can be contentious but is important in resisting Whiteness and working for inclusive and respectful principles (Benjamin, 2003). The second principle is that antiessentialist principles and practices must be maintained throughout when organizing from an anti-Black racism perspective. This principle means that there is no way of phenotypically or culturally being identified as Black. Black is intersected and interlocked with different social identities (e.g., Black is intersected with social identities of class, age, cultural backgrounds, sexual identities, and disabilities). This means that anti-Black racism must attend to the diverse voices and perspectives, and the differing political positions of the organizers in a respectful and inclusive manner (Benjamin, 2003).

A third principle concerns a deep ongoing commitment to continuous leadership of giving time, energy, and other resources as a requirement in organizing from an anti-Black racism perspective (Benjamin, 2003). The commitment to leadership in organizing must begin with a historic understanding that when Black leaders and organizations have attempted to make systemic change, their efforts have often been seen as untenable and unacceptable by those in power. Thus many community leaders and organizations have come under attack by the state (Benjamin, 2002, 2003; Williams, 2005). Leaders must therefore be skilled in strategy and tactic to challenge attacks by those in power who attempt to redirect or refuse to engage with their demands for systemic change in racist policies and practices. Benjamin (2003) argues that "naming racism and anti-Black racism is, consequently and critically, a form of resistance to White, capitalist hegemony and domination. To not name racism is often to give ground to those hegemonic forces that mask racism…under the guise of seemingly liberal and democratic notions of equality" (p. 80). Anti-Black racism offers a framework for theorizing about power and privilege that enables whiteness and white supremacy to be exposed (Dei, 2000). Anti-Black goes beyond race to tackle and work toward the development of a just and equitable society.

Today, implementing the concept of anti-Black racism in social work is difficult, as racism has been exacerbated by neoliberal policies, globalization, and the phenomena of color blindness in the Obama era of purported postraciality. Nevertheless, putting forward the concept of anti-Black racism is critical in moving the profession toward addressing racism, colonialism, and white supremacy in Canadian society. The profession must address such questions as: Where are the programs and courses on race? If they exist, are they addressing questions of anti-Black racism? How many Black faculty members are being hired in schools of social work? How many faculty members have scholarship that includes anti-Black racism? How many Black students are registered in social work programs? Do schools recognize that due to racism in their lives, Black students may need additional support and mentoring, or to speak with a faculty member who understands their issues? Addressing these questions is vital in moving anti-Black racism theory and action forward.

Conclusion

The silencing of antiracism by anti-oppression reinforces Canada's aversion to speaking about racism and colonialism, and consequently social work scholars have proposed instead anti-Black racism and anticolonialism. The rich tradition of Aboriginal and Black Canadian resistance to racism and colonialism offers social work education and practice a critical pedagogy of survival and social transformation. There is in Canada a wealth of knowledge and experience among Aboriginal and racialized elders, community leaders, activists, social workers, students, and scholars that is untapped in social work. Our histories however have often been erased from official classroom textbooks. Anti-Black racism and anticolonialism aim to propel social work to take action and reveal these hidden histories and ways of knowing that promise to fulfill the 1987 Canadian social work education commitment to "…prepare students to work effectively with diverse ethnic, cultural, and racial populations" (CASSW, 1991: p. 3).

Abstract

In contrast to the expectations of many researchers of modernity, ethnicity has become, today more than ever, a major aspect of the social reality. This article considers, defines, and distinguishes, in present-day terms, the notions of ethnic identity, identification, and identifying. It further delves into the sway of ethnicity in contemporary transformational processes as a factor in the multiculturalization of societies and diasporas.

Introduction

Ethnicity has constituted, in various forms, a characteristic aspect of many historical societies. The word derives from *ethnikos* and means 'heathen' in Greek (Spencer, 2006: 45); it was a conspicuous phenomenon in Athens, Rome, and Alexandria and was also a factor in the formation of the Indian caste system and the *millet* in Muslim societies. Ethnicity, as a rule, contributed to the establishing of segregation among segments of the population.

The rise of modernity, and with it the spread of new universalistic values and the construction of nation-states upholding concepts of nation and citizenship, led many scholars to believe that ethnicity was now doomed to lose its social significance. Social dynamics, however, would gainsay those expectations. Today, most observers cannot but acquiesce that ethnicity has in fact become a major driving force in contemporary social allegiances and transformations.

This article defines ethnicity in present-day terms, and elicits, in a sociological vein, its principal aspects which are considered here under the notions of collective identity, ethnic identification, and identifying. This phenomenon is linked to major developments in contemporary reality, analyzed in the final section.

Defining Ethnicity

Ethnicity is a notion that refers to social entities sharing real or putative ascriptive features like a common origin or cultural–linguistic legacy which assumedly command special collective commitment, as well as their retention and transmission (see Jenkins, 2007). While this definition is widely accepted – with diverse nuances – by researchers, divergences of views and understandings also divide them in certain respects, especially regarding the designation of factors accounting for the formation of ethnic bonds, or their dislocation. More particularly, an ongoing confrontation sets in conflict the primordialist and the circumstantialist. An early formulation of the 'primordialist' view was made by Shils (1957: 42) who argued that primordialism exists when "… a certain ineffable significance [is] attributed to the tie of blood." Geertz (1973: 259–260) added that the strength of such primordial bonds, and the types they illustrate

> …differ from person to person, from society to society, and from time to time. But for virtually every person, in every society, at all times, some attachments seem to flow more from a sense of natural – some would say spiritual – affinity than from social interaction.

It is in this vein that Bayar (2009) acknowledges that primordialism offers a convincing hypothesis in light of the persistence of ethnicity-related phenomena over long periods of time, in some groups. Support for this thesis is also offered by Cavalli-Sforza et al. (1994), who found that ethnic groups may have statistically significant distinctive genetic features.

The 'circumstantialist' or 'constructivist' perspective, in contrast, is a reminder that individuals have multiple identities. These allegiances are constructed and reconstructed over time in different contexts. Changing individual and social interests (Ratcliffe, 2010; Stone and Dennis, 2003) account satisfactorily for this dynamism. One of the first formulations of this approach by Fredrik Barth (1969: 6) stated that

> Ethnicity is a matter of social organization above and beyond questions of empirical cultural differences…[it is a matter of] self-ascription and ascription by others in interaction.

Andreas Wimmer (2008) elaborates a taxonomy of strategies for ethnic boundary construction and reconstruction. He points out the practice of redrawing collective boundaries by including new members, excluding marginal segments, or challenging the hierarchical ordering of social categories.

Another debate relates to the identities that should be included in the general notion of ethnic identity. Jenkins (2007) distinguishes racial, national, regional, local, and communal identities but argues at the same time that all these identities are simply conceptual variations of the more general type of collective identity, consisting of ethnicity. Not everyone, however, endorses this kind of outlook. Van den Bergh (1967: 9) drew a distinction between ethnicity as 'socially defined on the basis of cultural criteria' and race, which is 'socially defined on the basis of physical criteria.'

Eriksen (1993) adds that an ethnic group proper never completely overlaps the nation.

For the purpose of conceptual clarity, one may propose here that ethnicity designates this general kind of collective identity of a group – which may itself be subdivided in different manners – whose members are aware that they share a real or putative common ancestry. As such, they are engaged, in Giddens' (1991) words, in a reflexive project of identity building. Like any kind of collective-identity building, this project assumes that: (1) in one way or another, individuals feel committed to people whom they see as fellow-members of their group; (2) they perceive that group as conveying some cultural singularity; and (3) they tend, to some extent and in certain respects, to distance themselves from *others* whom they consider nonmembers (Ben-Rafael, 2001). This notion of ethnic identity which focuses on the awareness of individuals, describes an essentially subjective phenomenon and, as such, can never be seen as acquired permanently. It may involve dilemmas alongside unambiguous assertions; it may be phrased in different (possibly even contradictory) terms, diachronically or synchronically, among different circles pertaining to the same group.

These definitions are not opposed to constructionist interpretations that explore contextual aspects to explain identity elaborations. On the other hand, neither do these definitions exclude the primordialist principle. They recognize primordialism, not as independent of human will, but as an attribute that individuals perceive as given, and as conveying essential significance for them. Because of its subjective nature, however, that self-perceived singularity may also be formulated in different terms, as constructivists maintain, according to personalities, milieus, or circumstances.

Identification

Another dimension of ethnicity which is often confused with that notion of identity, but points in a different direction, consists of the issue of ethnic identification. Indeed, ethnic identification does not refer to the tenets of the collective identity but rather to the question of how much importance individuals ascribe to that identity. Like the formulations of identity itself, identification may vary greatly among fellow-ethnics and these variations are manifest in daily life, social norms, and involvement in collective goals. The highest degree of ethnic identification is illustrated by individuals who see their ethnic identity as their principal, if not only, collective identity; the lowest degree of identification is exemplified by individuals who completely disregard their ethnicity and view it just as an incidental 'origin.'

Though distinct dimensions of the ethnic condition, identity, and identification are never completely independent from each other. The weakening of ethnic identification may lead individuals to reformulate their ethnic identity in less precise terms. On the other hand, where religion is a component of a group's singularity, it often cements identification on the basis of transcendental convictions. In the words of Hervieu-Léger (2009: 447), faith presupposes submission to the religious authority which warrants the permanence of truth. Religions tend to explicitly convey a notion of exclusiveness over veracity (Sternberg, 2010). As assessed by Huntington (1993: 27) religion 'discriminates sharply' between people: A person may be half-French and half-Arab but it is much more difficult to conceive of being half-Catholic and half-Muslim. Hence, the religious revival witnessed in parts of the world today (Martin, 2010), particularly especially in its fundamentalist variants (see Almond et al., 2003), strengthens ethnoreligious cohesion as well as the potential for conflict between ethnic groups and other groups or individuals (Schnapper, 2005).

Other circumstances may also have an impact on identification. As Gold (2007) has shown, ethnic identification is strong in societies where populations are clearly differentiated by unequal participation in resources. This may lead to an ethnic division of labor in society, or even to split labor markets (Bonacich, 1972). In this respect, Light and Gold (2000) speak of an ethnic economy where a certain ethnic group takes control of given professional branches and staff most positions – from command echelons to rank-and-file. Such situations result in growing ethnic identification and retention of ethnic markers, motivated by economic objectives (Lichter, 2007).

The political regime, the configuration of power in society, and opportunities for building a constituency are other factors likely to influence ethnic identification. Since democracy is grounded in competition for support between parties and leaders, groups of many kinds – like local communities, professional categories, and class-oriented lobbies – may be able to build up constituencies and caucuses. This includes ethnic groups articulating identity politics (Calhoun, 1994; Bernstein, 2005; Saha, 2007). Political entrepreneurs belonging to ethnic entities may exploit available opportunities, and the more successfully they gather public support, the greater their contribution to the recognition of their *folk* and the legitimization of their constituency as a political actor. This kind of legitimization is in fact the imposition, bottom–up, of multiculturalism as societal reality (Ben-Rafael, 2010).

That legitimization is not, however, always unwelcomed by the dominant culture, which may even encourage it. By dominant culture, we refer to the beliefs, values, and symbols sustained by society's leading political forces and which express how those forces interpret the historical legacy and long-range interests of the setting. Among other issues, this dominant culture involves basic attitudes toward social–cultural heterogeneity as features of the social order. It may encourage groups to abandon their particularism on behalf of prevailing norms and values, or to retain their particularism jointly with the endorsement of the dominant culture's hard-core principles and symbols, at the least. In Germany, for instance, the dominant culture has long emphasized the notion of *Volk* (people) and its anchorage in history and language (Brubaker, 1992). Until recently, people of non-German origin, even those living in the country for decades, continued to be seen as outsiders. In the United States of today, contrastingly, the 'salad-bowl' metaphor (Hollinger, 1995) does not preclude groups from inserting themselves in society and becoming full members, while retaining some particularistic markers. In France, 'republicanism' defines the nation as a 'community of citizens' (Schnapper, 2005) and expects new groups to fully assimilate.

All in all, the group's socioeconomic condition – whether underprivileged or better-off, the nature of the dominant culture's approach to the group – whether segregative or assimilationist, and the group's own aspirations regarding insertion in society – whether moved by the drive to fully assimilate into the mainstream or to retain markers of distinctiveness, contribute in various ways to the emergence or retention of ethnicity. Hence, socioeconomically underprivileged ethnics, an exclusionist attitude of the dominant culture vis-à-vis the group, and a strong dedication of ethnics to their singular markers should, together, contribute to the group's confinement to the social margins, and its forming a kind of *enclave*. On the other hand, socioeconomic mobility of the group's members, an inclusionist dominant culture, and a flexible and open form of collective self-perception among the people concerned, in fact advance acculturation, and beyond it, tendencies to *assimilation*. Midway, one finds intermediary cases illustrating various possibilities. A socially mobile group would therefore be likely to acculturate eagerly to the mainstream culture, though the extent to which it tends to assimilate is still influenced by the openness of the dominant culture. Where a discrepancy exists between the group's general deprivation and the dominant culture's openness, one might expect mobile elements within the group to leave it and try to assimilate on their own. This, however, is contingent on the group itself generally aspiring to fusion with the mainstream. If it does not, one would rather expect that some of the mobile elements remain faithful to their group and resist the temptation of assimilation (see Ben-Rafael, 2001 for detailed hypotheses).

In all these, we should recall that the background of many contemporary cases of ethnicity consists of the experience of migration (Banton, 2008). Most of the time, immigrants who reach a target society demonstrate an irresistible tendency to grow more and more similar to mainstream society (Brubaker, 2001). However, the ethnic boundaries do not necessarily become totally blurred, even when former migrants acquire the dominant language and norms (Alba and Nee, 2003, 2007). On this point, researchers have suggested the concept of 'segmented' assimilation to indicate that upward mobility, far-reaching acculturation, and partial assimilation of a large part of a given ethnic group may occur through persistent combined biculturalism (Vermeulen, 2010).

It should also be noted that cultural convergence does not necessarily entail the disappearance or weakening of ethnic identification – especially when insertion does not take place in a highly favorable context. Different groups of immigrants coexisting in the same environment easily become hostile to each other in the context of difficulties in obtaining access to social resources. On the other hand, immigrants may also arouse among long-established citizens anti-immigrant feelings and nativism among people who consider themselves 'true' nationals and feel socially, economically, or culturally threatened by the newcomers. Sometimes, these 'nativists' turn to violent actions as a means of intimidation, or to direct national politics in order to impose restrictive measures against immigration (see Sternberg, 2009; Schrag, 2010; Lucassen, 2005). One thinks here of Le Penism in France and similar phenomena in Germany, Austria, and the Netherlands. However, such exclusionist and hostile manifestations tend rather to strengthen immigrants' ethnic identification.

Indentifying and Being Identified

This latter aspect brings out the additional issue of how *others* see ethnics and identify them. This identifying may be appreciative or neutral, but it is quite often rather negative and loaded with prejudice and stereotypes. These *others* are ethnics' fellow-countrymen in general, who may themselves respond to a wide diversity of labeling. Hence, at the societal level, this identifying repeats itself with each particular group and demarcates the multiple lines of the multicultural segmentation of society.

Identifying is thus a distinct aspect of the discourse about ethnicity which, however, is often confused with the notions of identity and identification. Identity, we saw, refers to the tenets of a group's collective identity, while identification investigates the importance that individuals grant that identity. Identifying, for its part, designates how people or institutions refer to individuals as members of a given group: It may be based on errors of discernment and eventually influence the individuals concerned in one way or another (ultimately by effectively identifying themselves as ethnics). However, identifying per se does assess the identity, let alone the identification of people in ethnic terms: when someone perceives a person as a 'Turk' or a 'Jew' this does not in itself make that person a Turk or a Jew. This does not belie the fact that being identified by a given ethnic label always has consequences for the individual concerned – especially when the identifier possesses power and has hostile intentions.

In actual fact, identifying actors in precise ethnic terms is by no means an easy task in present-day reality. Ethnic groups, indeed, are by no means impermeable to the influence of their environment and over time, volens nolens, attenuate their cultural particularism by converging toward the mainstream culture. In this, they come to exemplify what scholars designate as *cultural hybridization*, a notion that describes a given culture's acquisition of behavior patterns and values that a different one adheres to. The result, according to Jan Nederveen Pieterse (2000), consists of cultural alterations and changes that lead in turn to greater fluidity of collectives' social boundaries. Hence, collective boundaries have nowadays come to resemble dotted lines rather than clearly traced traits. In such circumstances, people quite easily find opportunities for slipping away from their group. Once outside the group, they may join other groups – which often happens through marriage – or locate themselves in the nonethnic category where the only feeling of attachment and commitment is toward the dominant culture and the national society as a whole. Multiculturalism, indeed, consists of a condition where sociocultural groups coexist and pressurize society in various directions but where more than a few people – possibly even a majority – do not perceive themselves as ethnics, and see in the nation or the national society their only meaningful attachment.

This does not signify, however, that individuals who see themselves as nonethnics may still be wrongly identified as ethnics by those around them (Kukutai and Didham, 2012), and here lies a major loophole for ethnicity statistics (Simon and Piché, 2012). As a rule, some studies use

observable 'objective' criteria like names, skin color, or place of residence in order to identify ethnic categories which in fact do not necessarily overlap the 'subjective' criteria referring to identity and identification. This conceptual clarification is especially important at a time when ethnicity is exercising an enormous impact on social reality, as it does nowadays.

Present-Day Impacts: Diaspora and Transnationality

Many cases of present-day ethnicity display another major characteristic that adds to the phenomenon's importance as a factor driving society toward new horizons. We refer, in the context of present-day globalization, to advances in communication and transportation technology and the new configurations of international relations, enabling ethnic groups dispersed worldwide to stay interconnected enduringly and on a daily basis with fellow-ethnics settled elsewhere as well as – where relevant – with their original homeland. Diaspora has always designated a commitment that goes beyond its literally significance in Greek, i.e., *dispersion* (διασπορά) (Dufoix, 2008). This commitment means that dispersed people stemming from the same cultural or territorial origin constitute a *transnational entity* (see Glick Schiller et al., 1995; Cohen, 1997). This entity, whose boundaries cut across state borders, is in many cases structured by institutions of its own which contribute to diasporans' retention of their collective identity and identification. As shown by Robin Cohen (2009), in some cases, the diasporans' identity is cemented by powerful myths and forms a *solid*-diaspora model, while in others it exemplifies a more *liquid* model influenced by the local culture and marked by less sacred icons (Waldinger, 2011).

The formation of transnational entities is most of the time the outcome of intercountry and intercontinent migration. Other possibilities or particular forms of migration are also illustrated by recent history. Hence, Rogers Brubaker (2009) speaks of the 'accidental diaspora' that develops as a result of the demise of political entities and border changes – illustrated by the Russian population living in the Baltics who became ethnic minorities in newly independent states. Another manifestation of transnationality consists of migrants from different groups who find themselves close – socially, culturally, or linguistically – to each other, and relatively remote from the mainstream in the host society. Such groups may tend to amalgamate into a kind of *pan-diaspora*. Latin-Americans of different origins who become *Hispanics* in the United States are an example, as are *Arab Muslims* of diverse origins in Europe. This does not rule out situations in which Mexicans or Cubans, on the one hand, and Moroccans or Algerians on the other, may concomitantly continue displaying their specific identities.

Still another pattern is the *returning diaspora* consisting of people of a given origin who, for whatever reasons, decide to *come home* and resettle in their or their ancestors' original homeland. In the meantime, they have absorbed another culture, have experienced the transformation of their legacy, and adopted new visions of the world. Good examples are Brazilian Japanese (Tsuda, 2003) resettling in Japan, or Ethnic Germans from Ukraine and Russia who resettle in Germany (Münz, 2002). Such groups may become an ethnic group in their new/old country by inversion of their collective identities: What was their ethnic identity now becomes their national identity, and what was their national identity, their ethnic identity.

One of the factors that may still encourage diasporans to consider going *back home* consists of the special relations their *original homeland's* government and other various organizations often retain with their nationals abroad. The first motive of these institutions, as well as of the basic positive response by diasporans to these efforts, is probably a general feeling of national solidarity. A second and more concrete motive appears to be the fact that governments of original *homelands* may find it beneficial to nurture strong relations with communities abroad when these have become significant political actors and could support their interests (Laguerre, 2006). On the other hand, diasporans who wish to achieve public power in their society of residence may also find the backing of homelanders to be beneficial. These games belong to identity politics which strengthens groups' ethnic identification but which, by the same token, fosters society's fragmentation as well (Ben-Rafael, 2010).

Moreover, groups of diasporans do not only contribute to the multiculturalization and fragmentation of their societies but also to the multiculturalization of their own diasporas. While diasporans' retention of ethnicity – even in the form of biculturalism – erodes the cohesion of their societies of residence, the prints left by the latter on the diverse communities attached to the same diaspora tend to transform the latter into a disparate entity.

All in all, ethnicity is a major factor in the transformation of contemporary societies at the local level and a lever for multicultural transnationalism globally. It contributes to the advent of a new societal and global (dis)order (Ben-Rafael, 2010; Ben-Rafael and Sternberg, 2009). Contrary to past predictions, contemporary ethnicity has by no means disappeared. On the contrary, in a diversity of forms and interpretations, it plays a role of its own in transforming the social world.

Abstract

Ethnoarchaeology is an important kind of middle-range research, consisting of ethnographic fieldwork undertaken by archaeologists. Ethnoarchaeologists study the material traces of ongoing human behavior so that archaeologists can better infer past human behavior from material patterns. Ethnoarchaeological fieldwork has been conducted all over the world, in settings ranging from hunting-gathering camps to state-level societies, and addresses a wide variety of material remains and artifact classes. Work focusing on refuse disposal and midden formation is highlighted in this article to illustrate ethnoarchaeology's contributions and relevance for the archaeological record.

Archaeologists study human societies, as do other anthropologists, but they study them primarily through their material culture (Renfrew and Bahn, 2012). The public may think of archaeologists such as those studying Maya culture, painstakingly toiling in Honduras to collect sixth-century artifacts from a site like Copán. These scholars do not observe Classic Maya society directly, but instead see the end products of behavior, such as artifacts, features, and spatial patterns.

How do archaeologists make sense of the archaeological record to learn about the people who created it? They must study the relationships between human behavior and material culture (Reid et al., 1974, 1975), specifically developing links or correlates between dynamic events and activities and their static material traces (Schiffer, 1975). This study of cause and effect has been labeled 'middle-range research' (Binford, 1978). Ethnoarchaeology is an important kind of middle-range research, consisting of ethnographic fieldwork undertaken by archaeologists. Ethnoarchaeologists study the material traces of ongoing human behavior so that archaeologists can better infer past human behavior from material patterns.

Other disciplines offer information on the material traces of ongoing human behavior too, including sociocultural anthropology, history, sociology, and geography. Data originally collected for nonarchaeological applications may be extremely useful to archaeologists, but is often too vague on crucial points of interest. An archaeological perspective is important for understanding "the relationships of material culture to culture as a whole" (David and Kramer, 2001: 2). Other labels for ethnoarchaeology include action archaeology, living archaeology, or archaeological ethnography.

Applying ethnoarchaeological data to archaeological cases (and the use of middle-range research in general) requires the use of cross-cultural generalizations, albeit with defined limits (or boundary conditions) to their applications (David and Kramer, 2001). One early example is Ascher's (1961) claim that analogies can be drawn between cultures that adapted to similar environments in similar ways. In this respect, ethnoarchaeology differs from the direct-historical approach, which applies knowledge of a group's current or recent culture to the study of its prehistory and depends upon cultural continuity over time. Although Jesse Walter Fewkes was the first to use the term 'ethnoarchaeologist' in 1900, Fewkes meant an archaeologist using the direct-historical approach and not an ethnoarchaeologist as currently defined (David and Kramer, 2001).

Ethnoarchaeology among hunter-gatherers may have had the biggest impact on archaeological interpretation, at least as measured in citation rates in *American Antiquity* articles (Skibo, 2009). Two recent applications of hunter-gatherer ethnoarchaeology include the use of data on site structure to interpret an open-air Paleoindian site (Bamforth et al., 2005) and use of data on long-distance logistical mobility to interpret middle Holocene sites in the Great Lakes region (Lovis et al., 2005). But the field of ethnoarchaeology is quite broad, conducted all over the world in settings ranging from hunting-gathering camps to state-level societies (see overview by David and Kramer, 2001). Topics include a wide variety of material remains and artifact classes, such as architecture, faunal bone, botanical remains, basketry, flaked stone, ceramics, glass, and metals. Activities and cultural processes have also been studied, such as the use of space within buildings, sites and settlements, and broader landscapes; site abandonment; and the development and transition of decoration and style.

The Development of Modern Ethnoarchaeology

In their book *Ethnoarchaeology in Action*, David and Kramer (2001) divide the history of ethnoarchaeology into three periods – Initial, New Ethnoarchaeology, and Recent – and I follow this framework and their characterization of these periods. The Initial period is mostly explorative and descriptive. David and Kramer mark the beginning of modern ethnoarchaeology with Maxine Kleindienst and Patty Jo Watson's (1956) paper *Action archaeology: the archaeological inventory of a living community*, in which Kleindienst and Watson argue that archaeologists rather than cultural anthropologists need to conduct ethnoarchaeological fieldwork. Other landmark studies in this period include Raymond Thompson's (1958) *Modern Yucatecan Maya Pottery Making* and George Foster's (1960) article *Life expectancy of utilitarian pottery in Tzintzuntzan, Michoacan, Mexico*, both of which explicitly consider archaeological application of their data.

The orientation of ethnoarchaeology shifted with the development of the New Archaeology or processual archaeology (e.g., Binford, 1962; *see* Theory in Archaeology; Archaeology: Philosophy and Science), producing the New Ethnoarchaeology. Processual archaeologists often use ethnoarchaeology as a source of testable hypotheses within an explicitly scientific framework. A related school of thought, behavioral archaeology, promotes using ethnoarchaeology to develop 'laws' that relate variables in behavior and material culture (Schiffer, 1978).

With its focus on environmental adaptation, the New Archaeology directed ethnoarchaeology toward studies of landscape and resource use. Many classic ethnoarchaeological studies of foragers were conducted during this period in the 1960s and 1970s, including work with the Ngatatjara Aborigines in Australia (e.g., Gould, 1980), the !Kung San in Southern Africa (e.g., Yellen, 1977), the Nunamiut in Alaska (e.g., Binford, 1978), and the Alyawara of central Australia (e.g., O'Connell and Hawkes, 1984). Influential studies of agricultural villagers from this period include research by Patty Jo Watson and Carol Kramer in Iran (e.g., Kramer, 1982; Watson, 1979) and William Longacre in the Philippines (e.g., Longacre, 1974).

David and Kramer (2001) start the Recent period with the publication of Ian Hodder's (1982) book *Symbols in Action*, in which Hodder argues that artifacts are not only passive end products of behavior, but also active participants in culture. This period is characterized not only by the continuation of New Ethnoarchaeology research agendas and projects, but also by the growing influence of post-processualism, which downplays function and adaptation and emphasizes the role of human choice and agency in culture. The sociologist Pierre Bourdieu and his practice theory became influential for Hodder and for many subsequent archaeologists.

Throughout the Recent period and up to the present, we see the rewards of three decades or more of modern ethnoarchaeology. They include published results from multiyear research projects such as work with the Hadza in Tanzania (e.g., O'Connell et al., 1988), the 1970s fieldwork of the Coxoh Ethnoarchaeology Project in the Maya highlands (e.g., Hayden and Cannon, 1984), the 1970s and later fieldwork of the Kalinga Ethnoarchaeological Project (e.g., Longacre and Skibo, 1994; Stark and Skibo, 2007), and the 1980s and later fieldwork of the Mandara Archaeological Project in Cameroon and Nigeria (e.g., David et al., 1988). They also include volumes that collect ethnoarchaeological data from multiple projects and regions, along with other kinds of data, to illuminate a particular topic. Examples are single-authored monographs such as Dean Arnold's (1985) *Ceramic Theory and Cultural Process*, Richard Blanton's (1993) *Houses and Households: A Comparative Study*, and Robert Kelly's (1995) *The Foraging Spectrum*, and edited volumes such as *Ceramic Ethnoarchaeology* (Longacre, 1991), *The Interpretation of Archaeological Spatial Patterning* (Kroll and Price, 1991), *Domestic Architecture and the Use of Space* (Kent, 1991), *The Ethnoarchaeology of Refuse Disposal* (Staski and Sutro, 1991), *From Bones to Behavior* (Hudson, 1993), and *Ethnozooarchaeology* (Albarella and Trentacoste, 2011). These synthetic works make use of global "cross-cultural comparisons as a uniformitarian strategy for learning in anthropology," as advocated by Lewis Binford (2001: 5) throughout his career.

Not all archaeologists believe ethnoarchaeology can produce scientific law-like generalizations about the relationships between human behavior and material culture, or that such generalizations can be applied broadly enough to be meaningful or useful (e.g., Hegmon, 2000). The long-term impact of classic ethnoarchaeological works is being reassessed by a recent series in the journal *Ethnoarchaeology: Journal of Archaeological, Ethnographic, and Experimental Studies*, which features retrospective essays by prominent ethnoarchaeologists coupled with an outside review. The profiled ethnoarchaeologists and works include not only Dean Arnold and *Ceramic Theory and Cultural Process* (Arnold, 1985, 2011; Harry, 2011), as cited above, but also Patty Jo Watson and *Archaeological Ethnography in Western Iran* (Kamp, 2010; Watson, 1979, 2010) and Richard Gould and *Living Archaeology*, which addresses Aboriginal lifeways in Australia (Gould, 1980, 2011; Holdaway and Allen, 2011). The area-focused works by Watson (1979) and Gould (1980) provide not only analogies for interpreting specific archaeological patterns, but also broaden the debate about the applicability of cross-cultural patterns. In spite of vigorous argument by both authors that their findings have cross-cultural relevance, they are most relied upon by archaeologists within their respective regions. Both works also underscore the complexity of the interactions between people and objects, and include information of broader anthropological interest with perhaps no clear archaeological application. In contrast, Arnold (1985) compiles data from multiple sources to create explicitly cross-cultural models, some of which (such as the distance to resources model) have been very widely applied. All of these prominent ethnoarchaeologists and many others have helped to bring a greater understanding of anthropological context into archaeological work, with or without the production of specific, widely used correlates.

Ethnoarchaeology is still a vibrant, productive discipline, as shown by publications in the last decade, with work continuing among both foraging and agricultural societies (e.g., Arthur, 2006; Jones, 2009; Lupo, 2006; Politis, 2007; Searcy, 2011). In addition to *Ethnoarchaeology*, which began publication in 2009, ethnoarchaeological work also frequently appears in other outlets including the journals *American Antiquity*, *Journal of Archaeological Method and Theory*, *Journal of Archaeological Science*, and in particular *Journal of Anthropological Archaeology*.

Ethnoarchaeology at Work: The Study of Refuse Deposits

To illustrate a deliberate cross-cultural approach to the application of ethnoarchaeological results, I turn to examples of ethnoarchaeology's contributions in the area of refuse or midden deposits. Refuse deposits are vitally important to the archaeologist, because most of the archaeological records consist of intentionally discarded objects. To make valid archaeological interpretations from them, we need to understand how items reach these deposits, how to determine which households or activity areas supply refuse to a particular deposit, and how the sample of material culture here represents material culture in use. If we come from industrialized state-level societies, the refuse disposal systems

of the societies we study are often very different from our own. Ethnoarchaeology is a valuable strategy to bridge the gap in our understanding, helping us to see the general principles of refuse disposal in different settings and to model how these deposits formed in archaeological cases (see papers in Staski and Sutro, 1991).

People handle refuse in different ways depending upon the density of settlement and the length of occupation (Schiffer, 1987; Wilson, 1994). Primary refuse, discarded where the activity took place, is more likely during brief occupations with outside activities. Secondary refuse is moved away from the use location for disposal, in increasingly formal ways with increasing population density. Formal, repeatedly used secondary refuse deposits are known as middens (Needham and Spence, 1997). Modern U.S. residents may rarely, if ever, see their middens on steroids – landfills – in which their discarded materials rest, and determining where a specific household's trash goes is a real challenge (Royte, 2006). In smaller communities and less formalized refuse disposal systems, including those earlier in U.S. history (Crane, 2000), the catchment areas of middens are smaller and physically closer.

Several communities studied ethnoarchaeologically – including the Maya in Chiapas, Mexico (Deal, 1985, 1998; Hayden and Cannon, 1983), households in the Sierra de los Tuxtlas of Veracruz, Mexico (Arnold, 1990), and the Shipibo-Conibo in the Peruvian Amazon (DeBoer and Lathrap, 1979) – have household midden accumulations immediately around the perimeter of the house clearing or house lot. Eventually, as documented in Chiapas, these deposits (known as 'toft' deposits) might be hauled away to ravines or neighborhood dumps (Hayden and Cannon, 1983: 146, Table 1).

A different midden accumulation pattern was seen in a small rural village in the mountains of northern Luzon, the Philippines, where there is limited availability of flat surfaces for building increased settlement density. Working as part of the Kalinga Ethnoarchaeological Project, Beck and Hill (Beck, 2006; Beck and Hill, 2004) documented 32 active middens in a community with 70 households. Even though household trash was not always sent to tofts or household middens next to the house lot, the catchment area of most middens could be reconstructed. Most households sent their daily household waste to only one midden, although some used two or three. Even when a household used more than one midden, however, it sent most of its waste to only one. The middens themselves were divided into groups based on how many households were in the catchment area. Household middens were used by only one household (receiving trash from, on average, 6 m away). Local middens were used by 2–5 households (receiving trash from, on average, 11 m away), and communal middens were used by six or more households (receiving trash from, on average, 35 m away). Household and local midden users travel less distance to discard material because they tend to live around the village exterior or next to an empty house lot, and therefore have the space for a midden by the house. Communal midden users live in the more densely occupied areas of the village and, with houses rather than empty space on all or most sides, must use a midden located in some other portion of the village. All the communal middens are located along the central axis of the village.

In marked contrast to modern U.S. discard behavior (Rathje and Murphy, 1992; Rathje et al., 1992), edible food for humans and materials that can be reused or recycled do not make it into ethnoarchaeological middens (Beck, 2006). Materials with any potential, whatsoever, are kept instead in 'provisional discard' (Deal, 1985: 259) near houses. Adult humans therefore do not scavenge in middens, but animals do, and dogs in particular take a heavy toll on discarded faunal remains. Children play in middens as well, breaking up objects that entered the midden in larger pieces and moving items around (see Hammond and Hammond, 1981). If trash deposits start to interfere with village needs (for example, if they become too large or too smelly, or if they sit on land now desired for another purpose), they will be moved or cleaned up by burning. This disturbance reduces the average ceramic sherd size significantly.

Ethnoarchaeological studies of modern garbage make important research contributions not only to archaeology, but to social science more broadly. The Garbage Project was founded at the University of Arizona in 1971 by faculty member William Rathje (Rathje and Murphy, 1992; Rathje et al., 1992). A Harvard-trained archaeologist who had previously studied the Classic Maya, Rathje used archaeological techniques to investigate modern household trash. This was a very productive way to examine modern household behavior and address social problems such as food waste and rapid landfill accumulation. The accumulation of nonbiodegradable trash is increasingly a problem in areas with limited space for disposal (see Jones et al., 2012 for a case on the small Fijian island of Nayau).

Garbage Project data were so illuminating, in part, because they proved to be a necessary complement to other research techniques. There were marked differences in data from the 'front door' (interviews) versus 'back door' (garbage). Garbage, as a nonreactive measure of behavior, "is the evidence of what people *did*, not what they *think* they did, what they think they should have done, or what they think the interviewer thinks they should have done" (Harrison et al., 1975: 13). For example, food consumption and food waste patterns were very different in the garbage versus survey data, with vast underreporting of food waste and alcohol consumption and vast overreporting of vegetable consumption. The Garbage Project illustrates that informants may not provide complete or accurate, and that material culture is another important line of information.

Ethnoarchaeology, as we now know it, has been part of our discipline for over 50 years. In that time, it has increased our understanding of the role of material culture in human lives – often (but not always) in ways that help us interpret material patterning in the archaeological record. Many archaeologists study societies very different from their own and do so indirectly because they can only observe the results of activities, not the activities themselves. Ethnoarchaeology cannot directly show us the people we seek to understand, but it can help us infer what they did, by providing better knowledge of comparable economies, crafts, and activities as well as site formation principles.

Ethnocentrism

Abstract

The term ethnocentrism passed from social science theory into common English usage during the twentieth century. In present usage it means the belief that one's culture is superior to others the use of a frame of reference derived from one's own culture to judge the arrtibutes of another culture, often in disparaging terms. The term was apparently invented in 1906 by the sociologist William Graham Sumner, who conceptualized it as a means of promoting solidarity within what he called 'ingroups' and antagonism toward 'outgroups.' He claimed ethnocentrism in this sociological as well as cultural sense to be a universal tendency of intergroup relations among humans. After 1950 Sumner's theory came under criticism from sociologists, who argued that individuals often belong to multiple groups and often admire outgroups, and from anthropologists, who described parts of the world in which ethnic identities, and thus alliances and antagonisms, were unstable historically. As Sumner's sociological formulation and claims of universality lost credibility, the vlaue of the ethnocentrism concept as a descriptor of recurrent attitudes gave it a permanent home in the English language.

Ethnocentrism is a term that passed from the social sciences into broader English discourse during the twentieth century. In current usage, it means culturally biased judgment, i.e., applying the frame of reference provided by one's culture to an object, action, person, or group of a different culture. The term as introduced by William Graham Sumner in his seminal treatise *Folkways* (Sumner, 1906) was explicitly sociological and included biased judgment as one of several features in a theory linking group solidarity with intergroup antagonism as a universal characteristic of human societies. Sumner's theory influenced research on ethnic relations and nationalism during the first half of the twentieth century. Later, the critique of Sumner by Merton and Rossi (1957) gave attention to the concept of ethnocentrism as problematic in social research, and LeVine and Campbell (1972) used the term as a rubric under which to review theories of inter- group relations and attitudes and to construct a framework for comparative research on the subject. By the end of the century, however, interest in ethnocentrism as a sociological concept had waned, even as the adjective 'ethnocentric' was commonly used as a descriptor or epithet in discussions of intercultural attitudes.

Sumner's brief but dense and multifaceted discussion of ethnocentrism in *Folkways* remains a primary source of theory on this subject. Although Sumner acknowledged previous work by the Austrian sociologist Ludwig Gumplowicz and Coser (1956) has cited Marx and other earlier theorists for certain aspects of ethnocentrism, Sumner himself may have coined the term ethnocentrism (as well as 'ingroup' and 'outgroup') and was responsible for endowing it with wide-ranging theoretical implications for the social sciences:

> The conception of 'primitive society' which we ought to form is that of small groups scattered over a territory. … A group of groups may have some relation to each other … which draws them together and differentiates them from others. Thus a differentiation arises between ourselves, the we-group, or in-group, and everybody else, or the others-group, out-groups. The insiders in a we-group are in a relation of peace, order, law, government and industry, to each other. Their relation to all outsiders, or others-groups, is one of war and plunder, except so far as agreements have modified it … .
>
> .. *Sentiments in the in-group and towards the out-group.* The relation of comradeship and peace in the we-group and that of hostility and war towards others-groups are correlative to each other. The exigencies of war with outsiders are what makes peace inside, lest internal discord should weaken the we-group for war. These exigencies also make government and law in the in-group, in order to prevent quarrels and enforce discipline. Thus war and peace have reacted on each other and developed each other, one within the group, the other in the intergroup relation. … Sentiments are produced to correspond. Loyalty to the group, sacrifice for it, hatred and contempt for outsiders, brotherhood within, warlikeness without – all group together, common products of the same situation. These relations and sentiments constitute a social philosophy. It is sanctified by connection with religion.
>
> … Virtue consists in killing, plundering, and enslaving outsiders.
>
> ... *Ethnocentrism* is the technical name for this view of things in which one's own group is the center of everything, and all others are scaled and rated with reference to it. Folkways correspond to it to cover both the inner and the outer relation. Each group nourishes its own pride and vanity, boasts itself superior, exalts its own divinities, and look with contempt on outsiders. Each group thinks its own folkways the only right ones, and if it observes that other groups have other folkways, these excite its scorn. Opprobrious epithets are derived from these differences. 'Pig-eater', 'cow-eater', 'uncircumcised', 'jabberers', are epithets of contempt and abomination. The Tupis called the Portuguese by a derisive epithet descriptive of birds which have feathers around their feet, on account of trousers. . For our present purpose the most important fact is that ethnocentrism leads a people to exaggerate and intensify everything in their own folkways which is peculiar and which differentiates them from others. It therefore strengthens the folkways (Sumner, 1906: pp. 12–13).

This passage shows both the scope of Sumner's discussion – covering attitudes and stereotypes as well as social relationships, organizational features and warfare – and his commitment to the theory that ingroup-outgroup dynamics generate internal solidarity and cultural coherence as well as hostility and warfare. Sumner claimed these dynamics and the concomitant attitudes to be universal in human societies, although he was aware that not all peoples were warlike. Social scientists before and after Sumner discovered many of the same phenomena in their own

research, but his influential passage became a point of reference for subsequent social theory and research on war and peace, ethnic relationships, and intergroup conflicts and attitudes.

Ethnocentrism as a process simultaneously promoting ingroup solidarity and outgroup hostility has been described at different levels, in many places and historical periods, not only by sociologists and anthropologists but also by political scientists, historians, and journalists. It is as familiar now, particularly in ethnic politics, as it was in Sumner's time. But Sumner's theoretical claims have been criticized and largely rejected by sociologists and anthropologists. Merton and Rossi (1957), in formulating the sociological theory of reference groups, pointed out that individuals often belong to, or wish to belong to, more than one group, making the ingroup-outgroup boundary ambiguous and the outgroup often an object of admiration rather than contempt. They argued that the ethnocentrism syndrome as Sumner formulated it should be seen as a special case of human intergroup relations rather than universal, as he claimed.

Anthropologists have been similarly critical. Describing many parts of the world where ethnic groups do not have bounded territories and individuals and groups change ethnic affiliation, anthropologists cast serious doubt on generalizations presuming that human groups have clear boundaries and stable membership (Leach, 1954; Barth, 1956, 1969; Goody, 1956; Moerman, 1965; LeVine and Campbell, 1972: pp. 81–113). Furthermore, the threat-dependent ethnic and national identities that Sumner assumed were products of a natural human tendency have increasingly been seen by anthropologists as deliberately constructed by leaders to gain adherents and seize power. Finally, it now seems likely that the intense nationalism and threatening military competition of the Western world in 1906 predisposed Sumner and his readers to accept ethnocentrism as a universal fact of human social life in advance of the comparative evidence. With better evidence and a different experience of international relations, we are less inclined to accept his theory.

Thus the sociology of Sumner's ethnocentrism syndrome, viewed in the light of recent evidence and newer perspectives, seems a dated fallacy of early twentieth century social science. The central problem has been that without clear and stable boundaries between ingroup and outgroup, the question of whether ingroup solidarity and outgroup hostility are consistently interdependent cannot be unequivocally answered. Group boundaries, if they ever were clear, have become more and more blurred as international migration and communication have intensified. Sumner's concept, as he generalized it, is not an accurate guide to the real world, but the question arises, if Sumner's formulation of the ethnocentrism syndrome has no merit as social theory, why does it seem so familiar as ethnographic description? How it is that, despite globalization, the contemporary world produces so many examples of conflict between ethnic groups differing in language, religion, and other customary practices, with mutual disparagement and threat-dependent solidarity escalating to intergroup violence? Answering this question through social research requires the investigation of the ethnocen-trism syndrome as a contingent historical phenomenon, examining in detail how the ideological and organizational patterns to which Sumner called attention have emerged in particular cases and how long they have lasted.

The term ethnocentrism remains in use to refer to culturally biased judgment, the act of applying the frame of reference from one's own culture to someone or something belonging to another culture. The *Dictionary of Anthropology* (Barfield, 1997: p. 55) defines ethnocentrism as 'the belief that one's own culture is superior to others, which is often accompanied by a tendency to make invidious comparisons. In a weaker form, ethnocentrism is the tendency to look at other cultures through the filter of one's own cultural presuppositions.' As in Sumner's examples in the passage quoted, ethnocentric judgments are usually derisive epithets, in which outgroup practices that deviate from ingroup norms form the basis for an insulting characterization: 'pig-eaters,' 'uncircum-cised,' 'jabberers.' This can reflect a naive form of ethnocentrism, called phenomenal absolutism by Segall et al. (1966), in which a person unreflectively takes his own culture's values as objective reality and automatically uses them as the context in which he judges less familiar objects and events. Alternatively, it can reflect a judgment made with full knowledge of cultural variability, but with an equally or even more scornful attitude. An ethnocentric judgment can be treated as a cognitive phenomenon, but it has emotional component as well. In its cultural form it is usually called an ethnic stereotype. Such stereotypes were intensively studied in American social psychology before and after World War II, up to the mid- 1950s (Allport, 1954). Since then, there has been relatively little research on ethnic stereotypes, but the concepts of ethnocentrism and stereotypes are still widely used in the mass media, in programs of training in intercultural communication, and in public discussions of racial prejudice and ethnic relations. The teaching of anthropology, through publications as well as in the classroom, is often justified by its role in reducing the ethnocentric attitudes ofWestern populations.
